## Chapter 1

## Leonardo of Pisa and the Fibonacci Sequence

Fibonacci, the pen name of Leonardo of Pisa which means son of Bonacci, was born in Pisa, Italy around 1170. Around 1192 his father, Guillielmo Bonacci, became director of the Pisan trading colony in Bugia, Algeria, and some time thereafter they traveled together to Bugia. From there Fibonacci traveled throughout Egypt, Syria, Greece, Sicily, and Provence where he became familiar with Hindu-Arabic numerals which at that time had not been introduced into Europe.

He returned to Pisa around 1200 and produced Liber Abaci in 1202. In it he presents some of the arithmetic and algebra he encountered in his travels, and he introduces the placevalued decimal system and Arabic numerals. Fibonacci continued to write mathematical works at least through 1228, and he gained a reputation as a great mathematician. Not much is known of his life after 1228, but it is commonly held that he died some time after 1240, presumably in Italy.

Despite his many contributions to mathematics, Fibonacci is today remembered for the sequence which comes from a problem he poses in Liber Abaci. The following is a paraphrase:

A man puts one pair of rabbits in a certain place entirely surrounded by a wall. The nature of these rabbits is such that every month each pair bears a new pair which from the end of their second month on becomes productive. How many pairs of rabbits will there be at the end of one year?

If we assume that the first pair is not productive until the end of the second month, then
clearly for the first two months there will be only one pair. At the start of the third month the first pair will beget a pair giving us a total of two pair. During the fourth month the original pair begets again but the second pair does not, giving us three pair, and so on.

Assuming none of the rabbits die we can develop a recurrence relation. Let there be $F_{n}$ pairs of rabbits in month $n$, and $F_{n+1}$ pairs of rabbits in month $n+1$. During month $n+2$, all the pairs of rabbits from month $n+1$ will still be there, and of those rabbits the ones which existed during the $n^{\text {th }}$ month will give birth. Hence $F_{n+2}=F_{n+1}+F_{n}$. The sequence which ensues when $F_{1}=F_{2}=1$ is called the Fibonacci sequence and the numbers in the sequence are the Fibonacci numbers.

| $n:$ | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | $\ldots$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $F_{n}:$ | 1 | 1 | 2 | 3 | 5 | 8 | 13 | 21 | 34 | 55 | 89 | 144 | $\ldots$ |

Thus the answer to Fibonacci's problem is 144.
Interestingly, it was not until 1634 that this recurrence relation was written down by Albert Girard.

Despite its simple appearance the Fibonacci sequence contains a wealth of subtle and fascinating properties. For example,

Theorem 1.1 Successive terms of the Fibonacci sequence are relatively prime.

Proof: Suppose that $F_{n}$ and $F_{n+1}$ are both divisible by a positive integer $d$. Then their difference $F_{n+1}-F_{n}=F_{n-1}$ will also be divisible by $d$. Continuing, we see that $d\left|F_{n-2}, d\right| F_{n-3}$, and so on. Eventually, we must have $d \mid F_{1}$. Since $F_{1}=1$ clearly $d=1$. Since the only positive integer which divides successive terms of the Fibonacci sequence is 1 , our theorem is proved.

One of the purposes of this chapter and the next is to develop many of the identities needed in chapters three and four. All of these can be found in either [4] or [20]. Given the recursive nature of the sequence, proof by induction is often a useful tool in proving identities and theorems involving the Fibonacci numbers. One of the most useful is the following.

Identity 1.2 $F_{m+n}=F_{m-1} F_{n}+F_{m} F_{n+1}$.

Proof: Let $m$ be fixed and we will proceed by inducting on $n$. When $n=1$, then $F_{m+1}=F_{m-1} F_{1}+F_{m} F_{2}=F_{m-1}+F_{m}$ which is true.

Now let us assume the identity is true for $n=1,2,3, \ldots, k$, and we will show that it holds for $n=k+1$. By assumption

$$
F_{m+k}=F_{m-1} F_{k}+F_{m} F_{k+1}
$$

and

$$
F_{m+(k-1)}=F_{m-1} F_{k-1}+F_{m} F_{k} .
$$

Adding the two we get $F_{m+k}+F_{m+(k-1)}=F_{m-1}\left(F_{k}+F_{k-1}\right)+F_{m}\left(F_{k+1}+F_{k}\right)$ which implies $F_{m+(k+1)}=F_{m-1} F_{k+1}+F_{m} F_{k+2}$ which is precisely our identity when $n=k+1$.

As an example of this identity, we see that $F_{12}=F_{8+4}=F_{7} F_{4}+F_{8} F_{5}=13(3)+21(5)=$ 144.

It is often useful to extend the Fibonacci sequence backward with negative subscripts. The Fibonacci recurrence can be written as $F_{n}=F_{n+2}-F_{n+1}$ which allows us to do this.

$$
\begin{array}{llccccccccccccc}
n: & \ldots & -7 & -6 & -5 & -4 & -3 & -2 & -1 & 0 & 1 & 2 & 3 & 4 & \ldots \\
F_{n}: & \ldots & 13 & -8 & 5 & -3 & 2 & -1 & 1 & 0 & 1 & 1 & 2 & 3 & \ldots
\end{array}
$$

Sequences such as the Fibonacci sequence which can be extended infinitely in both directions are called "bilateral".

With some inspection another useful identity presents itself:

Identity 1.3 $F_{-n}=(-1)^{n+1} F_{n}$.

Now we can combine the above two identities to obtain

Identity $1.4 F_{m-n}=(-1)^{n}\left(F_{m} F_{n+1}-F_{m+1} F_{n}\right)$

Another important fact about the Fibonacci sequence is easily tackled with induction.

Theorem 1.5 $F_{m} \mid F_{m n}$ for all integers $m, n$.

Proof: Let $m$ be fixed and we will induct on $n$. If either $m$ or $n$ equals zero, then the theorem is true by easy inspection. For $n=1$ it is clear that $F_{m} \mid F_{m}$.

Now let us assume that the theorem holds for $n=1,2, \ldots, k$ and we will show that it also holds for $n=k+1$. Using identity 1.2 we see $F_{m(k+1)}=$ $F_{m k-1} F_{m}+F_{m k} F_{m+1}$. By assumption $F_{m} \mid F_{m k}$, and so $F_{m}$ divides the entire right side of the equation. Hence $F_{m}$ divides $F_{m(k+1)}$ and the theorem is proved for $n \geq 1$. Since $F_{m n}$ differs from $F_{-m n}$ by at most a factor of -1 , then $F_{m} \mid F_{m n}$ for $n \leq-1$ as well.

A surprising result, with a surprisingly simple geometric proof is demonstrated in the following identity.

Identity $1.6 F_{1}^{2}+F_{2}^{2}+F_{3}^{2}+\cdots+F_{n}^{2}=F_{n} F_{n+1}$.

Proof: We can think of the squares of Fibonacci numbers as areas, and then put them together in the manner below.

We can find the area of the above rectangle by summing the squares, $F_{1}^{2}+F_{2}^{2}+$ $F_{3}^{2}+F_{4}^{2}+F_{5}^{2}+F_{6}^{2}$, or by multiplying height times width, $F_{6} \cdot\left(F_{5}+F_{6}\right)=F_{6} \cdot F_{7}$. The general case for the sum of the squares of $n$ Fibonacci numbers follows easily.

The following identity will be useful to us and it, too, can be proved geometrically.

Identity $1.7 F_{n}^{2}+F_{n+1}^{2}=F_{2 n+1}$.

## Proof:

The area above can be represented as $F_{n-1} F_{n+1}+F_{n} F_{n+2}$. From identity 1.2 this simplifies to $F_{n+(n+1)}=F_{2 n+1}$.

Here is another identity involving the square of Fibonacci numbers.

Identity $1.8 F_{n+1} F_{n-1}-F_{n}^{2}=(-1)^{n}$.

## Proof:

$$
\begin{aligned}
F_{n+1} F_{n-1}-F_{n}^{2} & =\left(F_{n-1}+F_{n}\right) F_{n-1}-F_{n}^{2} \\
& =F_{n-1}^{2}+F_{n}\left(F_{n-1}-F_{n}\right) \\
& =F_{n-1}^{2}-F_{n} F_{n-2} \\
& =-\left(F_{n} F_{n-2}-F_{n-1}^{2}\right) .
\end{aligned}
$$

We can now repeat the above process on the last line to attain

$$
\begin{aligned}
-\left(F_{n} F_{n-2}-F_{n-1}^{2}\right)= & (-1)^{2}\left(F_{n-1} F_{n-3}-F_{n-2}^{2}\right) \\
= & (-1)^{3}\left(F_{n-2} F_{n-4}-F_{n-3}^{2}\right) \\
& \vdots \\
= & (-1)^{n}\left(F_{1} F_{-1}-F_{0}^{2}\right) \\
= & (-1)^{n}
\end{aligned}
$$

It was the 19th century number theorist Edouard Lucas who first attached Fibonacci's name to the sequence we have been studying. He also investigated generalizations of the sequence.

A generalized Fibonacci sequence, $G$, is one in which the usual recurrence relation $G_{n+2}=G_{n+1}+G_{n}$ holds, but $G_{0}$ and $G_{1}$ may take on arbitrary values. The Lucas sequence, $L$, is an example of a generalized Fibonacci sequence where $L_{0}=2$ and $L_{1}=1$. It continues $2,1,3,4,7,11, \ldots$ There are many interesting relationships between the Fibonacci and Lucas sequences, and we give two of the most basic here.

Identity $1.9 L_{n}=F_{n-1}+F_{n+1}$.

Proof: We will prove the identity by induction. It is easy to see that $L_{1}=1=$ $0+1=F_{0}+F_{2}$ and $L_{2}=3=1+2=F_{1}+F_{3}$. Now suppose that the identity holds for $L_{r}$ and $L_{r+1}$ :

$$
\begin{aligned}
L_{r} & =F_{r-1}+F_{r+1} \\
L_{r+1} & =F_{r}+F_{r+2}
\end{aligned}
$$

Adding the two equations gives us $L_{r+2}=F_{r+1}+F_{r+3}$ and subtracting the top equation from the bottom yields $L_{r-1}=F_{r-2}+F_{r}$. Thus the identity holds for all positive and negative $r$.

Identity $1.10 \quad F_{2 n}=F_{n} L_{n}$.

Proof: $\quad F_{2 n}=F_{n+n}=F_{n-1} F_{n}+F_{n} F_{n+1}=F_{n}\left(F_{n-1}+F_{n+1}\right)=F_{n} L_{n}$.

We make a distinction between $a$ Fibonacci sequence, meaning any generalized Fibonacci sequence, and the Fibonacci sequence, meaning the sequence with $G_{0}=0$ and $G_{1}=1$.

Some authors generalize the sequence even more by using the relation $S_{n+2}=b S_{n+1}+$ $a S_{n}$. A further generalization examines sequences with the relation $S_{n}=c_{1} S_{n-1}+c_{2} S_{n-2}+$ $\cdots+c_{k} S_{n-k}$ for constants $k$ and $c_{i}$. Throughout this paper we will concentrate primarily on the Fibonacci sequence, though we will have occasion to make use of the generalized form $G_{n+2}=G_{n+1}+G_{n}$. We end this chapter with two identities from [20] involving the generalized Fibonacci sequence.

Identity $1.11 G_{m+n}=F_{n-1} G_{m}+F_{n} G_{m+1}$.

Proof: For the cases $n=0$ and $n=1$ we have

$$
\begin{aligned}
G_{m} & =F_{-1} G_{m}+F_{0} G_{m+1} \\
G_{m+1} & =F_{0} G_{m}+F_{1} G_{m+1}
\end{aligned}
$$

which is true since $F_{-1}=1, F_{0}=0$, and $F_{1}=1$. By adding the two equations it is easy to see that our identity continues to hold for $n=2,3, \ldots$ and so on. Subtracting the first equation from the second indicates that the identity also holds for negative $n$.

Identity 1.12 $G_{m-n}=(-1)^{n}\left(F_{n} G_{m+1}-F_{n+1} G_{m}\right)$

Proof: This identity follows by substituting $-n$ for $n$ in the above identity and then using identity 1.3 .

## Chapter 2

## The Binet Formula

While the recurrence relation and initial values determine every term in the Fibonacci sequence, it would be nice to know a formula for $F_{n}$ so we wouldn't have to compute all the preceding Fibonacci numbers. Such a formula was discovered by Jacques-Philippe-Marie Binet in 1843. Vajda [20] observes that this was actually a "rediscovery" since Abraham DeMoivre knew about this formula as early as 1718. However, history has favored Binet with the credit. Much of the material in this chapter can be found in [20].

Let us find the values for $x$ which will give us the generalized Fibonacci sequence $x^{n+2}=$ $x^{n+1}+x^{n}$. Since we are not concerned with the case where $x=0$ which gives us the trivial sequence, we may divide through by $x^{n}$ to attain $x^{2}=x+1$, that is, $x^{2}-x-1=0$. The two roots of this equation are

$$
\begin{equation*}
\tau=\frac{1+\sqrt{5}}{2} \quad \sigma=\frac{1-\sqrt{5}}{2} . \tag{2.1}
\end{equation*}
$$

Note the following properties of $\tau$ and $\sigma$ :

$$
\begin{equation*}
\tau+\sigma=1 \quad \tau-\sigma=\sqrt{5} \quad \tau \sigma=-1 \tag{2.2}
\end{equation*}
$$

Now $1, \tau, \tau^{2}, \tau^{3}, \ldots$ and $1, \sigma, \sigma^{2}, \sigma^{3}, \ldots$ are in fact generalized Fibonacci sequences since $\tau^{n+2}=\tau^{n+1}+\tau^{n}$ and $\sigma^{n+2}=\sigma^{n+1}+\sigma^{n}$. Indeed, any linear combination of $\tau^{n}$ and $\sigma^{n}$ forms the $n^{\text {th }}$ term of some Fibonacci sequence.

$$
\begin{equation*}
G_{n}=\alpha \tau^{n}+\beta \sigma^{n} \tag{2.3}
\end{equation*}
$$

As we see, $\left(\alpha \tau^{n}+\beta \sigma^{n}\right)+\left(\alpha \tau^{n+1}+\beta \sigma^{n+1}\right)=\alpha\left(\tau^{n}+\tau^{n+1}\right)+\beta\left(\sigma^{n}+\sigma^{n+1}\right)=\alpha \tau^{n+2}+\beta \sigma^{n+2}$.

Any Fibonacci sequence can be expressed this way for particular values of $\alpha$ and $\beta$. We show this by expressing $\alpha$ and $\beta$ in terms of $G_{0}, G_{1}, \tau$, and $\sigma$.

First, notice that $G_{0}=\alpha+\beta$ and $G_{1}=\alpha \tau+\beta \sigma$. Since $\beta=G_{0}-\alpha$ we can write

$$
\begin{aligned}
G_{1} & =\alpha \tau+\left(G_{0}-\alpha\right) \sigma \\
& =\alpha(\tau-\sigma)+G_{0} \sigma \\
& =\alpha \sqrt{5}+G_{0} \sigma
\end{aligned}
$$

which implies

$$
\begin{equation*}
\alpha=\frac{G_{1}-G_{0} \sigma}{\sqrt{5}} \tag{2.4}
\end{equation*}
$$

Similarly $\alpha=G_{0}-\beta$ and so

$$
\begin{aligned}
G_{1} & =\left(G_{0}-\beta\right) \tau+\beta \sigma \\
& =G_{0} \tau+\beta(\sigma-\tau) \\
& =G_{0} \tau-\beta \sqrt{5}
\end{aligned}
$$

which implies

$$
\begin{equation*}
\beta=\frac{G_{0} \tau-G_{1}}{\sqrt{5}} \tag{2.5}
\end{equation*}
$$

Now, once we know $G_{0}$ and $G_{1}$ we can use equations 2.4 and 2.5 to determine $\alpha$ and $\beta$, and then the formula for $G_{n}$ follows from equation 2.3.

For example, in the Fibonacci sequence $F_{0}=0$ and $F_{1}=1$, and so $\alpha=1 / \sqrt{5}$ and $\beta=-1 / \sqrt{5}$. Thus

$$
\begin{equation*}
F_{n}=\frac{\tau^{n}-\sigma^{n}}{\sqrt{5}} \tag{2.6}
\end{equation*}
$$

In the Lucas sequence $L_{0}=2$ and $L_{1}=1$.

$$
\begin{aligned}
& \alpha=\frac{1-2 \sigma}{\sqrt{5}}=\frac{(\tau+\sigma)-2 \sigma}{\sqrt{5}}=\frac{\tau-\sigma}{\sqrt{5}}=1 . \\
& \beta=\frac{2 \tau-1}{\sqrt{5}}=\frac{2 \tau-(\tau+\sigma)}{\sqrt{5}}=\frac{\tau-\sigma}{\sqrt{5}}=1 .
\end{aligned}
$$

Thus

$$
\begin{equation*}
L_{n}=\tau^{n}+\sigma^{n} . \tag{2.7}
\end{equation*}
$$

DeMoivre was able to derive the formula for $F_{n}$ in a different way, using generating functions. We demonstrate this technique next.

Let $g(x)=\sum_{i=0}^{\infty} F_{i} x^{i}$. It follows that $g(x)-F_{0} x^{0}-F_{1} x^{1}=g(x)-x$. Hence

$$
\begin{aligned}
g(x)-x & =\sum_{i=2}^{\infty} F_{i} x^{i}=\sum_{i=2}^{\infty}\left(F_{i-1} x^{i}+F_{i-2} x^{i}\right) \\
& =x \sum_{i=1}^{\infty} F_{i} x^{i}+x^{2} \sum_{i=0}^{\infty} F_{i} x^{i} \\
& =x g(x)+x^{2} g(x)
\end{aligned}
$$

Now we have $g(x)-x g(x)-x^{2} g(x)=x$. That is,

$$
\begin{aligned}
g(x) & =\frac{x}{1-x-x^{2}}=\frac{x}{1-(\tau+\sigma) x+\tau \sigma x^{2}} \\
& =\frac{x}{(1-\tau x)(1-\sigma x)}=\frac{(\tau-\sigma) x}{\sqrt{5}(1-\tau x)(1-\sigma x)} \\
& =\frac{1-\sigma x}{\sqrt{5}(1-\tau x)(1-\sigma x)}-\frac{1-\tau x}{\sqrt{5}(1-\tau x)(1-\sigma x)} \\
& =\frac{1}{\sqrt{5}(1-\tau x)}-\frac{1}{\sqrt{5}(1-\sigma x)} .
\end{aligned}
$$

Expressing $\frac{1}{1-\tau x}$ and $\frac{1}{1-\sigma x}$ as the sums of geometric series we get

$$
\begin{aligned}
g(x) & =\frac{1}{\sqrt{5}}\left(1+\tau x+\tau^{2} x^{2}+\cdots\right)-\frac{1}{\sqrt{5}}\left(1+\sigma x+\sigma^{2} x^{2}+\cdots\right) \\
& =\left[(\tau-\sigma) x+\left(\tau^{2}-\sigma^{2}\right) x^{2}+\cdots\right] / \sqrt{5}
\end{aligned}
$$

The coefficient of $x^{n}$, in other words $F_{n}$, is $\left(\tau^{n}-\sigma^{n}\right) / \sqrt{5}$, just as we suspected.
We can use the generating function to attain some unusual results. Taking our equation

$$
g(x)=\frac{x}{1-x-x^{2}}=\sum_{i=0}^{\infty} F_{i} x^{i}
$$

and dividing through by $x$ we get

$$
\begin{equation*}
\frac{1}{1-x-x^{2}}=\sum_{i=0}^{\infty} F_{i} x^{i-1} \tag{2.8}
\end{equation*}
$$

When $x=1 / 2$,

$$
4=\sum_{i=0}^{\infty} \frac{F_{i}}{2^{i-1}}
$$

which implies

$$
\begin{equation*}
2=\sum_{i=0}^{\infty} \frac{F_{i}}{2^{i}} \tag{2.9}
\end{equation*}
$$

Another remarkable summation identity is obtained by differentiating both sides of equation (2.8)

$$
\frac{1+2 x}{\left(1-x-x^{2}\right)^{2}}=\sum_{i=0}^{\infty}(i-1) F_{i} x^{i-2}
$$

When $x=1 / 2$,

$$
\begin{align*}
32 & =\sum_{i=0}^{\infty} \frac{(i-1) F_{i}}{2^{i-2}} \\
8 & =\sum_{i=0}^{\infty} \frac{(i-1) F_{i}}{2^{i}}=\sum_{i=0}^{\infty} \frac{i F_{i}}{2^{i}}-\sum_{i=0}^{\infty} \frac{F_{i}}{2^{i}} \\
8 & =\sum_{i=0}^{\infty} \frac{i F_{i}}{2^{i}}-2 \\
10 & =\sum_{i=0}^{\infty} \frac{i F_{i}}{2^{i}} . \tag{2.10}
\end{align*}
$$

The next identity is clearly more complicated than those we've looked at before, yet its proof yields readily to the Binet formula. The interesting thing about it is that it gives us insight into the recurrence relation governing subsequences of the Fibonacci sequence. This identity shows how every $n^{\text {th }}$ term of the Fibonacci sequence is related.

Identity 2.1 $F_{m+n}=L_{n} F_{m}+(-1)^{n+1} F_{m-n}$.

## Proof:

$$
\begin{aligned}
& L_{n} F_{m}+(-1)^{n+1} F_{m-n}=\left(\tau^{n}+\sigma^{n}\right)\left(\frac{\tau^{m}-\sigma^{m}}{\sqrt{5}}\right)+(-1)^{n+1}\left(\frac{\tau^{m-n}-\sigma^{m-n}}{\sqrt{5}}\right) \\
& =\frac{\tau^{m+n}-\tau^{n} \sigma^{m}+\sigma^{n} \tau^{m}-\sigma^{m+n}}{\sqrt{5}}+\frac{(-1)^{n+1} \tau^{m-n}-(-1)^{n+1} \sigma^{m-n}}{\sqrt{5}} \\
& =\frac{\tau^{m+n}-(-1)^{n} \sigma^{m-n}+(-1)^{n} \tau^{m-n}-\sigma^{m+n}-(-1)^{n} \tau^{m-n}+(-1)^{n} \sigma^{m-n}}{\sqrt{5}} \\
& =\frac{\tau^{m+n}-\sigma^{m+n}}{\sqrt{5}} \\
& =F_{m+n}
\end{aligned}
$$

It is easy to see that when $n=1$ in the above identity, we get the usual Fibonacci recurrence relation, $F_{m+1}=(1) F_{m}+(1) F_{m-1}$. When $n=m$ we get identity 1.10: $F_{2 n}=$ $L_{n} F_{n}$.

Identity $2.2 F_{n}=\frac{1}{2^{n-1}}\left[\binom{n}{1}+\binom{n}{3} 5+\binom{n}{5} 5^{2}+\binom{n}{7} 5^{3}+\cdots\right]$.
Proof:

$$
F_{n}=\frac{\tau^{n}-\sigma^{n}}{\sqrt{5}}=\frac{1}{2^{n} \sqrt{5}}\left[(1+\sqrt{5})^{n}-(1-\sqrt{5})^{n}\right]
$$

Now expand using the binomial theorem:

$$
\begin{aligned}
& =\frac{1}{2^{n} \sqrt{5}}\left[\left(1+\binom{n}{1} \sqrt{5}+\binom{n}{2} \sqrt{5}^{2}+\binom{n}{3} \sqrt{5}^{3}+\cdots\right)\right. \\
& \left.\quad-\left(1-\binom{n}{1} \sqrt{5}+\binom{n}{2} \sqrt{5}^{2}-\binom{n}{3} \sqrt{5}^{3}+\cdots\right)\right] \\
& =\frac{1}{2^{n-1} \sqrt{5}}\left[\binom{n}{1} \sqrt{5}+\binom{n}{3} \sqrt{5}^{3}+\binom{n}{5} \sqrt{5}^{5}+\cdots\right] \\
& =\frac{1}{2^{n-1}}\left[\binom{n}{1}+\binom{n}{3} 5+\binom{n}{5} 5^{2}+\binom{n}{7} 5^{3}+\cdots\right]
\end{aligned}
$$

Lastly in this chapter we use $\tau$ and $\sigma$ to demonstrate some simple greatest-integer identities. Though we will not use these, much research has been done in this area and they are certainly of interest in their own right.

Identity 2.3 $F_{n}=\left\lfloor\frac{\tau^{n}}{\sqrt{5}}+\frac{1}{2}\right\rfloor$ for all $n$.
Proof: $\left|F_{n}-\frac{\tau^{n}}{\sqrt{5}}\right|=\left|\frac{\sigma^{n}}{\sqrt{5}}\right|<\frac{1}{2}$ for all $n$.
Identity 2.4 $F_{n+1}=\left\lfloor\tau F_{n}+\frac{1}{2}\right\rfloor$ for $n \geq 2$.
Proof: $\quad\left|F_{n+1}-\tau F_{n}\right|=\left|\frac{\tau^{n+1}-\sigma^{n+1}}{\sqrt{5}}-\frac{\tau^{n+1}-\sigma^{n} \tau}{\sqrt{5}}\right|=\left|\frac{\sigma^{n}(\tau-\sigma)}{\sqrt{5}}\right|=\left|\sigma^{n}\right|<\frac{1}{2}$ for all $n \geq 2$.

## Chapter 3

## Modular Representations of Fibonacci Sequences

One way to learn some fascinating properties of the Fibonacci sequence is to consider the sequence of least nonnegative residues of the Fibonacci numbers under some modulus. One of the first modern inquiries into this area of research was made by D. D. Wall [22] in 1960, though J. L. Lagrange made some observations on these types of sequences in the eighteenth century. Typically, the variable $m$ will be used only to denote a modulus.

### 3.1 The Period

Perhaps the first thing one notices when the Fibonacci sequence is reduced $\bmod m$ is that it is periodic. For example,

$$
\begin{aligned}
& F(\bmod 4)=01123101123 \ldots \\
& F(\bmod 5)=0112303314044320224101123 \ldots
\end{aligned}
$$

See appendix C for a list of the Fibonacci sequence under various moduli.
Any (generalized) Fibonacci sequence modulo $m$ must repeat. After all, there are only $m^{2}$ possible pairs of residues and any pair will completely determine a sequence both forward and backward. If we ignore the pair 0,0 which gives us the trivial sequence, then we know that the period of any Fibonacci sequence $\bmod m$ has a maximum length of $m^{2}-1$.

It will always happen that the first pair to repeat will be the pair we started with. Suppose that this were not so. Then we might have the sequence $a, b, \ldots, x, y, \ldots, x, y, \ldots$ where the pair $a, b$ is not contained in the block $x, y, \ldots, x, y$. However, we know that this
block repeats backward as well as forward, and so the pair $a, b$ cannot be in the sequence. This gives us our contradiction.

We can say some things about where the zeros will appear in the modular representation of the Fibonacci sequence. Recall from identities 1.2 and 1.4 that

$$
\begin{aligned}
F_{s+t} & =F_{s-1} F_{t}+F_{s} F_{t+1} \\
F_{s-t} & =(-1)^{t}\left(F_{s} F_{t+1}-F_{s+1} F_{t}\right)
\end{aligned}
$$

If $F_{s} \equiv F_{t} \equiv 0$ then clearly $F_{s+t} \equiv 0$ and $F_{s-t} \equiv 0$. Hence all the zeros of $F(\bmod m)$ are evenly spaced throughout the sequence. Since $F(\bmod m)$ is periodic for any $m$ and $F_{0}=0$ we can say that any integer will divide infinitely many Fibonacci numbers. In addition, all the Fibonacci numbers divisible by a given integer are evenly spaced throughout the sequence.

We know that $F(\bmod m)$ is periodic, so the question naturally presents itself: What is the relationship between the modulus of a sequence and its period? We will examine some results in this area.

Each author seems to have his or her own notation, but the following definitions come from Wall. Let $k(m)$ denote the period of the Fibonacci sequence modulo $m$. Let $h(m)$ denote the period of any generalized Fibonacci sequence modulo $m$. From our previous example we see that $k(4)=6$ and $k(5)=20$. The following are some immediate consequences of the definition.

$$
\begin{align*}
F_{n} & \equiv F_{n+r \cdot k(m)} \quad(\bmod m) \\
G_{n} & \equiv G_{n+r \cdot h(m)} \quad(\bmod m) \\
F_{k(m)} & \equiv 0 \quad(\bmod m)  \tag{3.1}\\
F_{k(m)-1} & \equiv F_{k(m)+1} \equiv F_{k(m)+2} \equiv 1 \quad(\bmod m) \tag{3.2}
\end{align*}
$$

We will often use the fact that if $F_{n} \equiv 0(\bmod m)$ and $F_{n+1} \equiv 1(\bmod m)$ then $k(m) \mid n$. This result follows immediately from the periodicity of $F(\bmod m)$.

We now demonstrate some very general properties of $F(\bmod m)$ using our notation. The following three theorems can be found in [22]. The reader is encouraged to examine the table in appendix B which gives the period of $F(\bmod m)$ for $2 \leq m \leq 1000$, and observe the
behavior of $k(m)$ as $m$ varies. After noticing that $F(\bmod m)$ is periodic one notices that almost all of the periods are even. Though Wall provides the next theorem, the proof is the author's.

Theorem 3.1 For $m \geq 3, k(m)$ is even.

Proof: For ease of notation let $k=k(m)$, and we will consider all congruences to be taken modulo $m$. From identity 1.3 we know that if $t$ is odd then $F_{t}=F_{-t}$ and if $t$ is even then $F_{t}=-F_{-t}$. We will assume $k$ to be odd and show that $m$ must equal 2 .

We know that $F_{1}=F_{-1} \equiv F_{k-1}$. Now $k-1$ is even so $F_{k-1}=-F_{1-k} \equiv-F_{1}$. Thus $F_{1} \equiv-F_{1}$, and as a result $m=2$.

Another curious feature of $F(\bmod m)$ is that $k(n) \mid k(m)$ whenever $n \mid m$. Surprisingly, this property is true of generalized Fibonacci sequences as well.

Theorem 3.2 If $n \mid m$, then for a given Fibonacci sequence, $h(n) \mid h(m)$.

Proof: Let $h=h(m)$. We need to show that $G(\bmod n)$ repeats in blocks of length $h$. We do this by showing that $G_{i} \equiv G_{i+h}(\bmod n)$ regardless of our choice for $i$. Certainly we know that $G_{i} \equiv G_{i+h}(\bmod m)$, so for some $0 \leq a<m$ we have $G_{i}=a+m x$ and $G_{i+h}=a+m y$.

Now say $m=n r$ and let us substitute $n r$ for $m$ in the previous two equations. Then $G_{i}=a+n r x$ and $G_{i+h}=a+n r y$. We can say that $a=a^{\prime}+n w\left(0 \leq a^{\prime}<n\right)$ and this time substitute for $a$ in the previous equations. Now $G_{i}=a^{\prime}+n(w+r x)$ and $G_{i+h}=a^{\prime}+n(w+r y)$. Of course this implies that $G_{i} \equiv G_{i+h}(\bmod n)$ which was needed to be shown.

We can make this theorem more exact by expressing $h(m)$ in terms of $h\left(p_{i}^{e_{i}}\right)$ where $m$ has the prime factorization $m=\prod p_{i}^{e_{i}}$.

Theorem 3.3 Let $m$ have the prime factorization $m=\prod p_{i}^{e_{i}}$. Then $h(m)=\operatorname{lcm}\left[h\left(p_{i}^{e_{i}}\right)\right]$, the least common multiple of the $h\left(p_{i}^{e_{i}}\right)$.

Proof: By our previous theorem $h\left(p_{i}^{e_{i}}\right) \mid h(m)$ for all $i$. It follows that lcm $\left[h\left(p_{i}^{e_{i}}\right)\right] \mid h(m)$.
Second, since $h\left(p_{i}^{e_{i}}\right) \mid \operatorname{lcm}\left[h\left(p_{i}^{e_{i}}\right)\right]$ we know $G\left(\bmod p_{i}^{e_{i}}\right)$ repeats in blocks of length $\operatorname{lcm}\left[h\left(p_{i}^{e_{i}}\right)\right]$. Hence $G_{\operatorname{lcm}\left[h\left(p_{i}^{e_{i}}\right)\right]} \equiv G_{0}$ and $G_{\operatorname{lcm}\left[h\left(p_{i}^{e_{i}}\right)\right]+1} \equiv G_{1}\left(\bmod p_{i}^{e_{i}}\right)$ for all $i$. Since all the $p_{i}^{e_{i}}$ are relatively prime, the Chinese Remainder Theorem assures us that $G_{\operatorname{lcm}\left[h\left(p_{i}^{e_{i}}\right)\right]} \equiv G_{0}$ and $G_{\operatorname{lcm}\left[h\left(p_{i}^{e_{i}}\right)\right]+1} \equiv G_{1}(\bmod m)$. Thus $G(\bmod m)$ repeats in blocks of length $\operatorname{lcm}\left[h\left(p_{i}^{e_{i}}\right)\right]$ and we can say that $h(m) \mid \operatorname{lcm}\left[h\left(p_{i}^{e_{i}}\right)\right]$. This concludes the proof.

Hence we have reduced the problem of characterizing $k(m)$ into the problem of characterizing $k\left(p^{e}\right)$. Before we develop theorems which speak to this problem, however, we look at a related result. We see in the following theorem that it is not necessary to break a modulus all the way into its prime factorization in order to attain information about $k(m)$.

Theorem 3.4 $h([m, n])=[h(m), h(n)]$ where brackets denote the least common multiple function.

Proof: Since $m \mid[m, n]$ and $n \mid[m, n]$ we know that $h(m) \mid h([m, n])$ and $h(n) \mid h([m, n])$. It follows that $[h(m), h(n)] \mid h([m, n])$.

Say we have the prime factorization $[m, n]=p_{1}^{e_{1}} \ldots p_{t}^{e_{t}}$. Then $h([m, n])=$ $h\left(p_{1}^{e_{1}} \ldots p_{t}^{e_{t}}\right)=\left[h\left(p_{1}^{e_{1}}\right) \ldots h\left(p_{t}^{e_{t}}\right)\right]$. Since $p_{i}^{e_{i}}$ divides $m$ or $n$ for all $i$, certainly $h\left(p_{i}^{e_{i}}\right)$ divides $h(m)$ or $h(n)$ for all $i$. Thus $\left[h\left(p_{1}^{e_{1}}\right) \ldots h\left(p_{t}^{e_{t}}\right)\right][[h(m), h(n)]$. In other words, $h([m, n]) \mid[h(m), h(n)]$.

Hence $h([m, n])=[h(m), h(n)]$.

Now we turn our attention back to the matter of solving $k\left(p^{e}\right)$ in terms of $p^{e}$. The general case of this theorem is somewhat involved, so to motivate the ideas we look at a couple of specific cases. We will demonstrate that $k\left(2^{e}\right)=3 \cdot 2^{e-1}$ and $k\left(5^{e}\right)=4 \cdot 5^{e}$. These results can be found in [11], but the proofs there are somewhat incomplete. For example, Kramer and Hoggatt show that $F_{3 \cdot 2^{e-1}} \equiv 0\left(\bmod 2^{e}\right)$ and $F_{3 \cdot 2^{e-1}+1} \equiv 1\left(\bmod 2^{e}\right)$ and they immediately conclude that $k\left(2^{e}\right)=3 \cdot 2^{e-1}$. However, this only demonstrates that $k\left(2^{e}\right) \mid 3 \cdot 2^{e-1}$. The proof below takes this point into consideration.

Theorem $3.5 k\left(2^{e}\right)=3 \cdot 2^{e-1}$.

Proof: By inspection, $k(2)=3$ and $k(4)=6$, so the theorem holds for $e=1,2$. Suppose $k\left(2^{r}\right)=3 \cdot 2^{r-1}$, so that $F_{3 \cdot 2^{r-1}} \equiv 0$ and $F_{3 \cdot 2^{r-1}+1} \equiv 1\left(\bmod 2^{r}\right)$ and we will induct on $r$.

By identity 1.10 ,

$$
F_{3 \cdot 2^{r}}=\left(F_{3 \cdot 2^{r-1}}\right)\left(F_{3 \cdot 2^{r-1}-1}+F_{3 \cdot 2^{r-1}+1}\right)
$$

The first factor on the right, $F_{3 \cdot 2^{r-1}} \equiv 0\left(\bmod 2^{r}\right)$. It is an easy matter to see that every third Fibonacci number is even and the rest are odd, so the second factor on the right, $F_{3 \cdot 2^{r-1}-1}+F_{3 \cdot 2^{r-1}+1} \equiv 0(\bmod 2)$. Thus their product, $F_{3 \cdot 2^{r}} \equiv 0\left(\bmod 2^{r+1}\right)$.

By identity 1.7,

$$
\left.\begin{array}{rl}
F_{3 \cdot 2^{r}+1} & = \\
& \left(F_{3 \cdot 2^{r-1}}\right)^{2} \\
& \equiv \\
& \left(0 \text { or } 2^{r}\right)^{2} \\
& + \\
\equiv & 0 \\
& + \\
& \left(1 \text { or } 2^{r}+1\right)^{r-1}+1
\end{array}\right)\left(\bmod 2^{r+1}\right)
$$

Thus we know $k\left(2^{r+1}\right) \mid 3 \cdot 2^{r}$.
We know that $k\left(2^{r}\right) \mid k\left(2^{r+1}\right)$, and by our induction hypothesis $k\left(2^{r}\right)=3$. $2^{r-1}$. Thus $k\left(2^{r+1}\right)=$ either $3 \cdot 2^{r-1}$ or $3 \cdot 2^{r}$. We will show that the latter is true by proving $F_{3 \cdot 2^{r-1}+1} \not \equiv 1\left(\bmod 2^{r+1}\right)$. More precisely, we will prove that $F_{3 \cdot 2^{r-1}+1} \equiv 2^{r}+1\left(\bmod 2^{r+1}\right)$.

Let us add this statement to our induction hypothesis: assume $F_{3 \cdot 2^{r-2}} \equiv 0$ and $F_{3 \cdot 2^{r-2}+1} \equiv 2^{r-1}+1\left(\bmod 2^{r}\right)$. By inspection this is the case for $r=3$. We will induct on $r$ to show that $F_{3 \cdot 2^{r-1}+1} \equiv 2^{r}+1\left(\bmod 2^{r+1}\right)$.

By identity 1.7,

$$
F_{3 \cdot 2^{r-1}+1}=\left(F_{3 \cdot 2^{r-2}+1}\right)^{2}+\left(F_{3 \cdot 2^{r-2}}\right)^{2} .
$$

Let us look at the first term on the right.

$$
\begin{aligned}
F_{3 \cdot 2^{r-2}+1} & \equiv\left(2^{r-1}+1\right) \text { or }\left(2^{r-1}+1+2^{r}\right) \quad\left(\bmod 2^{r+1}\right) \\
\left(2^{r-1}+1\right)^{2} & =2^{2 r-2}+2^{r}+1 \equiv 2^{r}+1 \quad\left(\bmod 2^{r+1}\right) \\
\left(2^{r-1}+1+2^{r}\right)^{2} & =\left(3 \cdot 2^{r-1}+1\right)^{2} \\
& =9 \cdot 2^{2 r-2}+3 \cdot 2^{r}+1 \equiv 2^{r}+1 \quad\left(\bmod 2^{r+1}\right)
\end{aligned}
$$

Thus

$$
\left(F_{3 \cdot 2^{r-2}+1}\right)^{2} \equiv 2^{r}+1 \quad\left(\bmod 2^{r+1}\right)
$$

Let us look at the second term on the right.

$$
\begin{aligned}
F_{3 \cdot 2^{r-2}} & \equiv 0 \text { or } 2^{r} \quad\left(\bmod 2^{r+1}\right) \\
0^{2} & \equiv 0 \quad\left(\bmod 2^{r+1}\right) \\
\left(2^{r}\right)^{2} & =2^{2 r} \equiv 0 \quad\left(\bmod 2^{r+1}\right)
\end{aligned}
$$

Thus

$$
\left(F_{3 \cdot 2^{r-2}}\right)^{2} \equiv 0\left(\bmod 2^{r+1}\right)
$$

Consequently $F_{3 \cdot 2^{r-1}+1} \equiv 2^{r}+1\left(\bmod 2^{r+1}\right)$ and the theorem follows.

Before we prove a similar theorem for $k\left(5^{e}\right)$ we first need to mention a lemma which provides insight into one of the divisibility properties of the Fibonacci sequence.

Lemma 3.6 Let $p$ be an odd prime and suppose $p^{t} \mid F_{n}$ but $p^{t+1} \chi F_{n}$ for some $t \geq 1$. If $p \nmid v$ then $p^{t+1} \mid F_{n v p}$ but $p^{t+2} \chi F_{n v p}$.

The proof of this lemma is too involved to be examined here, but it can be found in [20].
Since $F_{5}=5$, clearly 5 goes into $F_{5}$ once. By the the lemma then, 5 goes into $F_{n \cdot 5^{t}}$ exactly $t$ times if $5 \nmid n$.

Theorem $3.7 k\left(5^{e}\right)=4 \cdot 5^{e}$.

Proof: First we will show that for all $e, F_{4 \cdot 5^{e}} \equiv 0$ and $F_{4 \cdot 5^{e}+1} \equiv 1\left(\bmod 5^{e}\right)$.
By the lemma above clearly $F_{4 \cdot 5^{e}} \equiv 0\left(\bmod 5^{e}\right)$. From identity 1.7 we have

$$
F_{4 \cdot 5^{e}+1}=\left(F_{2 \cdot 5^{e}}\right)^{2}+\left(F_{2 \cdot 5^{e}+1}\right)^{2} .
$$

Applying our lemma to the first term on the right gives us $\left(F_{2 \cdot 5^{e}}\right)^{2} \equiv 0^{2} \equiv$ $0\left(\bmod 5^{e}\right)$. By identity 1.8 , the second term on the right, $\left(F_{2 \cdot 5^{e}+1}\right)^{2}=F_{2 \cdot 5^{e}} F_{2 \cdot 5^{e}+2}+$ $(-1)^{2 \cdot 5^{e}+2} \equiv 1\left(\bmod 5^{e}\right)$.

Thus we know that $F_{4 \cdot 5^{e}} \equiv 0$ and $F_{4 \cdot 5^{e}+1} \equiv 1\left(\bmod 5^{e}\right)$ and it follows that $k\left(5^{e}\right) \mid 4 \cdot 5^{e}$ for all $e$.

We proceed now by induction using the hypothesis $k\left(5^{r}\right)=4 \cdot 5^{r}$. By inspection this is the case for $r=1$. We induct on $r$ to show $k\left(5^{r+1}\right)=4 \cdot 5^{r+1}$.

Since $4 \cdot 5^{r}=k\left(5^{r}\right) \mid k\left(5^{r+1}\right)$ and $k\left(5^{r+1}\right) \mid 4 \cdot 5^{r+1}$, we know $k\left(5^{r+1}\right)=$ either $4 \cdot 5^{r}$ or $4 \cdot 5^{r+1}$. In the first case, $F_{4 \cdot 5^{r}}$ contains exactly $r$ factors of 5 and hence $F_{4 \cdot 5^{r}} \not \equiv 0\left(\bmod 5^{r+1}\right)$. Hence we must have $k\left(5^{r+1}\right)=4 \cdot 5^{r+1}$ and our theorem is proved.

We have proved $k\left(p^{e}\right)=p^{e-1} k(p)$ for $p=2$ and $p=5$, and we now turn to proving it for all $p$. While the general theorem is slightly less strict than these special cases, it does give us great insight into the periodic behavior of the Fibonacci sequence. One proof, by Robinson[15], also shows how matrices may be used to discover facts about the Fibonacci sequence. We will be working with the matrix $U$ defined by

$$
U=\left[\begin{array}{ll}
0 & 1 \\
1 & 1
\end{array}\right]
$$

which has the property that

$$
U^{n}=\left[\begin{array}{cc}
F_{n-1} & F_{n}  \tag{3.3}\\
F_{n} & F_{n+1}
\end{array}\right] .
$$

This matrix has been called the Fibonacci matrix because of this property. Note that $U^{k(m)}=I+m B \equiv I(\bmod m)$ for some $2 \times 2 \operatorname{matrix} B$. And, if $U^{n} \equiv I(\bmod m)$ then $k(m) \mid n$.

Theorem 3.8 If $t$ is the largest integer such that $k\left(p^{t}\right)=k(p)$ then $k\left(p^{e}\right)=p^{e-t} k(p)$ for all $e \geq t$.

Proof: Since $U^{k\left(p^{e}\right)}=I+p^{e} B$ we can write $U^{p k\left(p^{e}\right)}=\left(I+p^{e} B\right)^{p}=I^{p}+$ $\binom{p}{1} I^{p-1}\left(p^{e} B\right)+\binom{p}{2} I^{p-2}\left(p^{e} B\right)^{2}+\cdots$. Thus $U^{p k\left(p^{e}\right)} \equiv I\left(\bmod p^{e+1}\right)$. Clearly $U^{k\left(p^{e+1}\right)} \equiv I\left(\bmod p^{e+1}\right)$ and so we have $k\left(p^{e+1}\right) \mid p k\left(p^{e}\right)$. Combine this fact with the knowledge that $k\left(p^{e}\right) \mid k\left(p^{e+1}\right)$ and as a result $k\left(p^{e+1}\right)=k\left(p^{e}\right)$ or $p k\left(p^{e}\right)$.

Now let us assume that $k\left(p^{e+1}\right)=p k\left(p^{e}\right)$ and we will induct on $e$ to arrive at $k\left(p^{e+2}\right)=p k\left(p^{e+1}\right)$.

By assumption $k\left(p^{e}\right) \neq k\left(p^{e+1}\right)$ and so we know that $U^{k\left(p^{e}\right)}=I+p^{e} B$ where $p \nmid B$. Hence $U^{p k\left(p^{e}\right)}=\left(I+p^{e} B\right)^{p}=I^{p}+\binom{p}{1} I^{p-1}\left(p^{e} B\right)+\binom{p}{2} I^{p-2}\left(p^{e} B\right)^{2}+\cdots \equiv$ $I+p^{e+1} B\left(\bmod p^{e+2}\right)$. (The astute reader may notice that this congruence does
not actually hold for $p=2, e=1$. However, since we have proven the case for $p=2$ in theorem 3.5 we may assume $p \geq 3$.) That is, $U^{k\left(p^{e+1}\right)}=U^{p k\left(p^{e}\right)} \equiv$ $I+p^{e+1} B \not \equiv I\left(\bmod p^{e+2}\right)$. This implies $k\left(p^{e+1}\right) \neq k\left(p^{e+2}\right)$ so we must have $k\left(p^{e+2}\right)=p k\left(p^{e+1}\right)$ and the induction is complete.

Now let $t$ be the largest $e$ such that $k\left(p^{e}\right)=k(p)$. Then $k\left(p^{e}\right)=k(p)$ for $1 \leq e \leq t$ and $k\left(p^{e}\right)=k\left(p^{e-t}\right)$ for $e \geq t$.

Remarkably, the conjecture that $t=1$ for all primes has existed since Wall's paper in 1960 , but neither a proof nor a counter example has yet been found. Once again we have been able to reduce the problem of finding the period of the Fibonacci sequence given a modulus. All that remains (other than proving $t=1$ for all primes, of course) is to characterize $k(p)$ in terms of $p$. However, this undertaking has proven to be extraordinarily difficult, and the best we can do is to describe some bounds on $k(p)$.

Theorems 3.11 through 3.13 will describe upper bounds on $k(p)$, but we must first take some time to develop certain divisibility properties of the Fibonacci sequence found in [20]. We will make use of these three facts for primes, $p$ :
(i) $\binom{p}{n} \equiv 0(\bmod p)$ for $1 \leq n \leq p-1$
(ii) $\binom{p-1}{n} \equiv(-1)^{n}(\bmod p)$ for $0 \leq n \leq p-1$
(iii) $\binom{p+1}{n} \equiv 0(\bmod p)$ for $2 \leq n \leq p-1$

We will also use the following lemma:

Lemma 3.95 is a quadratic residue modulo primes of the form $5 t \pm 1$ and a quadratic nonresidue modulo primes of the form $5 t \pm 2$.

Proof: Using the Legendre symbol and the law of quadratic reciprocity we know that $\left(\frac{5}{p}\right)=\left(\frac{p}{5}\right)$ since 5 is a prime of the form $4 t+1$. Then,

$$
\begin{aligned}
& \left(\frac{5}{5 t+1}\right)=\left(\frac{5 t+1}{5}\right)=\left(\frac{1}{5}\right)=1 \\
& \left(\frac{5}{5 t-1}\right)=\left(\frac{5 t-1}{5}\right)=\left(\frac{4}{5}\right)=1
\end{aligned}
$$

However,

$$
\begin{aligned}
& \left(\frac{5}{5 t+2}\right)=\left(\frac{5 t+2}{5}\right)=\left(\frac{2}{5}\right)=-1 \\
& \left(\frac{5}{5 t-2}\right)=\left(\frac{5 t-2}{5}\right)=\left(\frac{3}{5}\right)=-1
\end{aligned}
$$

Using identity 2.2 we have $2^{p-1} F_{p}=\binom{p}{1}+\binom{p}{3} 5+\cdots+\binom{p}{p} 5^{\frac{p-1}{2}}$. Applying (i) above and Fermat's theorem we get $F_{p} \equiv 5^{\frac{p-1}{2}}(\bmod p)$. Now from the lemma we know that $5^{\frac{p-1}{2}} \equiv 1(\bmod p)$ if and only if $p=5 t \pm 1$, and $5^{\frac{p-1}{2}} \equiv-1(\bmod p)$ if and only if $p=5 t \pm 2$. Hence,

If a prime $p$ is of the form $5 t \pm 1$ then $F_{p} \equiv 1(\bmod p)$.
If a prime $p$ is of the form $5 t \pm 2$ then $F_{p} \equiv-1(\bmod p)$.
The converse of these statements is not true, for in fact $F_{22}=17711=85(22)+1 \equiv$ $1(\bmod 22)$, and quite clearly, 22 is not prime.

Again we use identity 2.2 and see $2^{p-2} F_{p-1}=\binom{p-1}{1}+\binom{p-1}{3} 5+\cdots+\binom{p-1}{p-2} 5^{\frac{p-3}{2}}$. By (ii) above, $2^{p-2} F_{p-1} \equiv-\left(1+5+5^{2}+\cdots+5^{\frac{p-3}{2}}\right)(\bmod p)$. Summing the geometric series yields,

$$
2^{p-2} F_{p-1} \equiv-\frac{5^{\frac{p-1}{2}}-1}{4} \quad(\bmod p)
$$

Clearly if $5^{\frac{p-1}{2}} \equiv 1(\bmod p)$ then $2^{p-2} F_{p-1} \equiv 0(\bmod p)$. Certainly $2^{p-2} \not \equiv 0(\bmod p)$ so it would have to be that $F_{p-1} \equiv 0(\bmod p)$. Hence,

If a prime $p$ is of the form $5 t \pm 1$ then $F_{p-1} \equiv 0(\bmod p)$.
Finally, identity 2.2 gives us $2^{p} F_{p+1}=\binom{p+1}{1}+\binom{p+1}{3} 5+\cdots+\binom{p+1}{p} 5^{\frac{p-1}{2}}$. By (iii) above, $2^{p} F_{p+1} \equiv\binom{p+1}{1}+\binom{p+1}{p} 5^{\frac{p-1}{2}}=(p+1)+(p+1) 5^{\frac{p-1}{2}} \equiv 1+5^{\frac{p-1}{2}}(\bmod p)$. Now when $5^{\frac{p-1}{2}} \equiv-1(\bmod p)$ we will have $2^{p} F_{p+1} \equiv 0(\bmod p)$. Since $2^{p} \equiv 2(\bmod p)$, it would have to be that $F_{p+1} \equiv 0(\bmod p)$. Thus,

If a prime $p$ is of the form $5 t \pm 2$ then $F_{p+1} \equiv 0(\bmod p)$.
Collecting our results provides us with the following theorem.

Theorem 3.10 If a prime $p$ is of the form $5 t \pm 1$ then $F_{p-1} \equiv 0$ and $F_{p} \equiv 1(\bmod p)$. If a prime $p$ is of the form $5 t \pm 2$ then $F_{p} \equiv-1$ and $F_{p+1} \equiv 0(\bmod p)$.

Now at last we can present some theorems concerning the character of $k(p)$.

Theorem 3.11 If $p$ is a prime, $p \neq 5$, then $k(p) \mid p^{2}-1$.

Proof: By inspection, $k(2)=3$, and the theorem holds for $p=2$. Now let us assume $p$ odd. To prove the theorem we will show that $F_{p^{2}-1} \equiv 0$ and $F_{p^{2}} \equiv 1(\bmod p)$.

If $p=5 t \pm 1$ then $p \mid F_{p-1}$. We know that $p-1 \mid p^{2}-1$ and so $F_{p-1} \mid F_{p^{2}-1}$. Hence $p \mid F_{p^{2}-1}$. If $p=5 t \pm 2$ then $p \mid F_{p+1}$. We know that $p+1 \mid p^{2}-1$ and so $F_{p+1} \mid F_{p^{2}-1}$. Hence $p \mid F_{p^{2}-1}$. Thus for all $p \neq 5, F_{p^{2}-1} \equiv 0(\bmod p)$.

To prove $F_{p^{2}} \equiv 1(\bmod p)$, we first note that $2^{p^{2}-1} F_{p^{2}}=\binom{p^{2}}{1}+\binom{p^{2}}{3} 5+$ $\cdots+\binom{p^{2}}{p^{2}} 5^{\frac{p^{2}-1}{2}}$. Now $2^{p^{2}-1}=\left(2^{p-1}\right)^{p+1} \equiv 1(\bmod p)$ and $\binom{p^{2}}{n} \equiv 0(\bmod p)$ for $1 \leq n \leq p^{2}-1$. Hence $F_{p^{2}} \equiv\left(5^{\frac{p-1}{2}}\right)^{p+1} \equiv( \pm 1)^{p+1} \equiv 1(\bmod p)$.

Thus the theorem is proved.

Theorem 3.12 If a prime $p$ is of the form $5 t \pm 1$ then $k(p) \mid p-1$.

Proof: Since $p=5 t \pm 1$, theorem 3.10 tells us that $F_{p-1} \equiv 0$ and $F_{p} \equiv$ $1(\bmod p)$. Hence $F(\bmod p)$ repeats in blocks of length $p-1$. Thus $k(p) \mid p-1$.

Theorem 3.13 If a prime $p$ is of the form $5 t \pm 2$ then $k(p) \mid 2 p+2$.

Proof: Suppose $p=5 t \pm 2$. By theorem 3.10 then, $F_{p+1} \equiv 0(\bmod p)$. Since $p+1 \mid 2 p+2$ and the zeros of $F(\bmod p)$ are evenly spaced, we can say $F_{2 p+2} \equiv$ $0(\bmod p)$.

We also know that $F_{p} \equiv-1(\bmod p)$. By the usual recurrence relation then, $F_{p+2} \equiv F_{p+3} \equiv-1(\bmod p)$. Now we can write $F_{2 p+3}=F_{(p+1)+(p+2)}=$ $F_{p} F_{p+2}+F_{p+1} F_{p+3} \equiv(-1)(-1)+(0)(-1) \equiv 1(\bmod p)$.

Thus $k(p) \mid 2 p+2$.

We now consider upper and lower bounds for $k(m)$ where $m$ can be any integer $m \geq 2$. It was noted earlier that $k(m) \leq m^{2}-1$, but can we do better than this? One method of determining an upper bound is to use the two preceding theorems to show that $k(p)=p^{2}-1$ if and only if $p=2$ or 3 . Then by application of theorem 3.8 it can be proved that $k\left(p^{e}\right)<$ $\left(p^{e}\right)^{2}-1$ for $e \geq 2$. Finally, we can use theorem 3.4 to demonstrate that $k(m)<m^{2}-1$ for all composite $m$.

However, the author would like to propose a more elegant way of proving this inequality. If $k(m)=m^{2}-1$ for some $m$, then every possible pair of residues except 0,0 appears in $F(\bmod m)$. It will be seen in section 3.3 that a single period of $F(\bmod m)$ contains at most four zeros. Consequently, $F(\bmod m)$ contains at most four $0, r$ pairs where $1 \leq r<m$. Hence, for $m \geq 6$ there is some $0, r$ pair not represented in $F(\bmod m)$ and we must have $k(m)<m^{2}-1$. It is a simple matter to check the remaining cases. When $m=2$ or 3, $k(m)=m^{2}-1$ and when $m=4$ or $5, k(m)<m^{2}-1$.

Unfortunately, empirical evidence indicates that this upper bound becomes less and less precise as $m$ increases. For $2 \leq m \leq 299$ we find by inspection that $k(m) \leq 6 m$. For $300 \leq m \leq 1000$ we find $k(m) \leq 4 m$. There does not appear to be any other material published concerning upper bounds on $k(m)$.

A sharp lower bound on $k(m)$ was given by Paul Catlin[5] in 1974. We see here an interesting interaction between the Lucas and Fibonacci numbers. We present his theorem without proof.

Theorem 3.14 Given a modulus $m>2$, let $t$ be any natural number such that $L_{t} \leq m$. Then $k(m) \geq 2 t$ with equality if and only if $L_{t}=m$ and $t$ is odd.

In the beginning of the section we saw some results which helped to define the overall character of $h(m)$ and thus of $k(m)$. In the last part of this section we present some results due to Wall on the relationship between $h(m)$ and $k(m)$. The first of these is strikingly simple.

Theorem $3.15 h(m) \mid k(m)$.

Proof: For ease of notation, let $k=k(m)$. Applying identity 1.11 and then equations 3.1 and 3.2 we get $G_{k}=F_{k-1} G_{0}+F_{k} G_{1} \equiv G_{0}(\bmod m)$ and $G_{k+1}=$ $F_{k} G_{0}+F_{k+1} G_{1} \equiv G_{1}(\bmod m)$. Thus $G(\bmod m)$ repeats in blocks of length $k(m)$. From this we can conclude $h(m) \mid k(m)$.

We can elicit equality between $h(m)$ and $k(m)$ by putting stricter conditions on $m$.

Theorem 3.16 If a prime $p$ is of the form $5 t \pm 2$ then $h\left(p^{e}\right)=k\left(p^{e}\right)$.

Proof: For ease of notation, let $h=h\left(p^{e}\right)$. Certainly,

$$
\begin{aligned}
G_{h}-G_{0} & \equiv 0\left(\bmod p^{e}\right), \text { and } \\
G_{h-1}-G_{1} & \equiv 0\left(\bmod p^{e}\right) .
\end{aligned}
$$

By identity 1.11 the above is equivalent to

$$
\begin{aligned}
\left(F_{h-1} G_{0}+F_{h} G_{1}\right)-G_{0} & =G_{1} F_{h}+G_{0}\left(F_{h-1}-1\right) \equiv 0 \quad(\bmod p) \\
\left(F_{h-1} G_{1}+F_{h+1} G_{2}\right)-G_{1} & =G_{2} F_{h}+G_{1}\left(F_{h-1}-1\right) \equiv 0 \quad(\bmod p)
\end{aligned}
$$

We now have a system of equations which we may treat as a matrix with determinant $D=G_{1}^{2}-G_{0} G_{2}$. We will assume that $D \equiv 0(\bmod p)$ and arrive at a contradiction.

When $D \equiv 0(\bmod p)$ then $G_{1}^{2}-G_{0} G_{2}=G_{1}^{2}-G_{0}\left(G_{0}+G_{1}\right)=G_{1}^{2}-G_{0} G_{1}-$ $G_{0}^{2} \equiv 0(\bmod p)$. This last congruence is impossible if $p=2$ (we ignore the
trivial case $G_{0}=G_{1}=0$ ) so we may assume $p$ to be odd. Multiply both sides by -4 .

$$
4 G_{0}^{2}+4 G_{0} G_{1}-4 G_{1}^{2} \equiv 0 \quad(\bmod p)
$$

Add $5 G_{1}^{2}$ to both sides.

$$
4 G_{0}^{2}+4 G_{0} G_{1}+G_{1}^{2}=\left(2 G_{0}+G_{1}\right)^{2} \equiv 5 G_{1}^{2} \quad(\bmod p)
$$

Now multiply both sides by $G_{1}^{p-3}$ and apply Fermat's theorem to the right.

$$
G_{1}^{p-3}\left(2 G_{0}+G_{1}\right)^{2} \equiv 5 \quad(\bmod p)
$$

Since $p$ is odd, this implies that 5 is a quadratic residue modulo $p$. However, by lemma 3.9 , this contradicts our hypothesis that $p=5 t \pm 2$. Therefore, $D \not \equiv 0(\bmod p)$, and this implies that $D \not \equiv 0\left(\bmod p^{e}\right)$.

Since the determinant of our matrix is not congruent to zero $\left(\bmod p^{e}\right)$, it must have a unique solution modulo $p^{e}$. Certainly $F_{h} \equiv 0$ and $\left(F_{h-1}-1\right) \equiv$ $0\left(\bmod p^{e}\right)$ satisfy the system, and so $F_{h} \equiv 0$ and $F_{h-1} \equiv 1\left(\bmod p^{e}\right)$. From the recurrence relation, $F_{h+1} \equiv 1\left(\bmod p^{e}\right)$ as well.

Since $h=h\left(p^{e}\right)$ our results tell us that $k\left(p^{e}\right) \mid h\left(p^{e}\right)$. By theorem 3.15 we know $h\left(p^{e}\right) \mid k\left(p^{e}\right)$. Hence $h\left(p^{e}\right)=k\left(p^{e}\right)$.

Wall proved several other results regarding the relationship between $h(m)$ and $k(m)$. We present some of these here without proof. As usual, $p$ denotes a prime number.

Theorem 3.17 Let $D=G_{1}^{2}-G_{0} G_{1}-G_{0}^{2}$. If $\operatorname{gcd}(D, m)=1$ then $h(m)=k(m)$.
Theorem 3.18 If $h\left(p^{e}\right)=2 t+1$ for some generalized Fibonacci sequence, then $k\left(p^{e}\right)=$ $4 t+2$.

Theorem 3.19 If $p>2$ and $k\left(p^{e}\right)=4 t+2$ then there exists some generalized Fibonacci sequence where $h\left(p^{e}\right)=2 t+1$.

Theorem 3.20 Let $p$ be odd and $p \neq 5$. If $h\left(p^{e}\right)$ is even then $h\left(p^{e}\right)=k\left(p^{e}\right)$.

We end the section with two curious theorems pertaining to the period of $F(\bmod m)$ which did not seem to fit logically elsewhere within this section. We defer their proofs to the
end of section 3.3 where we will have developed other ideas sufficiently to make their proofs easy. The curious feature here is that the modulus of the sequence is an actual Fibonacci or Lucas number. Theorem 3.45 can be found in [7] and theorem 3.46 can be found in [17].

Theorem 3.45 If $n \geq 5$ is odd then $k\left(F_{n}\right)=4 n$. If $n \geq 4$ is even then $k\left(F_{n}\right)=2 n$.

Theorem 3.46 If $n \geq 3$ is odd then $k\left(L_{n}\right)=2 n$. If $n \geq 2$ is even then $k\left(L_{n}\right)=4 n$.

These theorems indicate that for any even $t \geq 6$ there is some $m$ such that $k(m)=t$. Also, $k(m)$ can not equal 4 , otherwise $F_{4}=3 \equiv 0$ and $F_{3}=2 \equiv 1(\bmod m)$ which is not possible. Hence the range of $k(m)$ is 3 union the set of all even numbers greater than or equal to 6 .

### 3.2 The Distribution Of Residues

In this section we look at what is known about the distribution of residues within a single period of $F(\bmod m)$. That is, how frequently each residue is expected to appear. We start off with a more specific question: for which moduli will all the residues appear with equal frequency within a single period? If $F(\bmod m)$ exhibits this property it is said to be uniform or uniformly distributed. Kuipers and Shiue[12] proved that the only time $F(\bmod m)$ can possibly be uniform is when $m=5^{e}$.

It is not difficult to see that if $F(\bmod m)$ is uniform, then necessarily $m \mid k(m)$. We use this requirement to prove that 5 is the only prime for which $F(\bmod p)$ is uniform.

We first note that by inspection $F(\bmod 2)$ is not uniform but $F(\bmod 5)$ is, with each residue appearing four times per period. Let us consider odd primes $p$.

If $p=5 t \pm 1$ then $F(\bmod p)$ cannot be uniform. For such $p$, we know $k(p) \mid p-1$, but $p \nmid p-1$ and so $p \nmid k(p)$.

If $p=5 t \pm 2$ then $F(\bmod p)$ cannot be uniform. In this case $k(p) \mid 2 p+2$, but for odd $p$ we know $p \nmid 2 p+2$. Hence $p \nmid k(p)$. Thus 5 is the only prime for which $F(\bmod p)$ is uniform.

Now we mention a second fact about uniform distribution: if $F(\bmod m)$ is uniform and $n \mid m$, then $F(\bmod n)$ is also uniform. Suppose $m=n r$. Then in one period of $F(\bmod m)$ each of the residues $0,1, \ldots, n-1$ occurs with equal frequency as do the residues $n, n+1, \ldots$,

Figure 3.1: Comparing residues $\bmod 5$ and $\bmod 25$. The residues $\bmod 25$ are "stratified" to display them more clearly.
$2 n-1$, and so on until $(r-1) n,(r-1) n+1, \ldots, r n-1$. Thus within $k(m)$ terms of $F(\bmod n)$ the residues $0,1,2, \ldots,(n-1)$ appear with equal frequency, say $t$ times. Since $k(n) \mid k(m)$ we can find these $k(m)$ terms by simply repeating the first $k(n)$ terms. If $\frac{k(m)}{k(n)}=u$, then within $k(n)$ terms each residue appears $\frac{t}{u}$ times. Hence $F(\bmod n)$ is uniform.

Putting these two facts together provides us with the following theorem.
Theorem 3.21 The only possible values of $m$ for which $F(\bmod m)$ is uniform are $m=5^{e}$.
It takes a very clever proof to finally settle the issue as we will demonstrate next. Niederreiter provided such a proof in [14].

Theorem 3.22 $F\left(\bmod 5^{e}\right)$ is uniform for all integers $e \geq 1$.
Before we start in earnest, we present the basic idea behind the proof. We know that $k\left(5^{e}\right)=4 \cdot 5^{e}$ and so "it will suffice to show that among the first $4 \cdot 5^{e}$ elements of the sequence, we find exactly four elements, or, equivalently, at most four elements from each residue class $\bmod 55^{e} . "$

For example, modulo 5 we see that the residue 3 appears exactly four times per period. Modulo 25 , the residues $3,8,13,18$, and 23 each appear exactly four times in one period. Each of the five sections in figure 3.1 represents one period $\bmod 5$, and the bottom portion shows where the residues $3,8,13,18$, and 23 appear in relation to the threes.

Proof: Let us assume that $F\left(\bmod 5^{r-1}\right)$ is uniform and we will use induction on $r$. We have seen that the hypothesis holds for $r=2$.

Consider integers $a$ and $b$ such that $0 \leq a<5^{r-1}$ and $0 \leq b<5^{r}$. (In the figure we show $a=3$ and $r=2$.) $F_{n} \equiv a\left(\bmod 5^{r-1}\right)$ has four solutions: $n=c_{1}$, $c_{2}, c_{3}, c_{4}$, with $0 \leq c_{1}, c_{2}, c_{3}, c_{4}<4 \cdot 5^{r-1}$. Suppose $b \equiv a\left(\bmod 5^{r-1}\right)$ and $n=d$ is a solution to $F_{n} \equiv b\left(\bmod 5^{r}\right)$ where $0 \leq d<4 \cdot 5^{r}$. Then $F_{d} \equiv a\left(\bmod 5^{r-1}\right)$. Hence by periodicity we must have $d \equiv c_{i}\left(\bmod 4 \cdot 5^{r-1}\right)$ for some $i$. We will show that there is only one solution $d$ such that $d \equiv c_{i}\left(\bmod 4 \cdot 5^{r}\right)$ for each $i$.

Suppose $m \equiv n\left(\bmod 4 \cdot 5^{r-1}\right)$ and $F_{m} \equiv F_{n}\left(\bmod 5^{r}\right)$. Let $0 \leq m, n<4 \cdot 5^{r}$, and without loss of generality, say $m \leq n$. We will prove that, in fact, $m=n$.

From identity $2.2, F_{n} \equiv F_{m}\left(\bmod 5^{r}\right)$ implies

$$
\sum_{j=0} 5^{j}\binom{n}{2 j+1} \equiv 2^{n-m} \sum_{j=0} 5^{j}\binom{m}{2 j+1} \quad\left(\bmod 5^{r}\right)
$$

Now $4 \cdot 5^{r-1} \mid n-m$ and by the Euler-Fermat theorem, $\phi\left(5^{r}\right)=5^{r}-5^{r-1}=4 \cdot 5^{r-1}$. Thus $2^{n-m} \equiv 1\left(\bmod 5^{r}\right)$. Hence we have,

$$
\begin{equation*}
\sum_{j=0} 5^{j}\left[\binom{n}{2 j+1}-\binom{m}{2 j+1}\right] \equiv 0 \quad\left(\bmod 5^{r}\right) \tag{3.4}
\end{equation*}
$$

Here we use the known identity $\binom{s+t}{u}=\sum_{i=0}^{u}\binom{s}{i}\binom{t}{u-i}$ to obtain $\binom{n}{2 j+1}=$ $\sum_{i=0}^{2 j+1}\binom{n-m}{i}\binom{m}{2 j+1-i}$. That is,

$$
\binom{n}{2 j+1}=\binom{m}{2 j+1}+\sum_{i=1}^{2 j+1}\binom{n-m}{i}\binom{m}{2 j+1-i} .
$$

Substituting this result into equation (3.4) gives us

$$
\sum_{j=0}\left[\sum_{i=1}^{2 j+1} 5^{j}\binom{n-m}{i}\binom{m}{2 j+1-i}\right] \equiv 0 \quad\left(\bmod 5^{r}\right)
$$

We claim that for $j \geq 1$ each term in brackets is divisible by $5^{r}$. Consider $5^{j}\binom{n-m}{i}=\frac{5^{j}(n-m)!}{i!(n-m-i)!}$. Cancelling out 5 's from $i$ ! against $5^{j}$ always leaves at least one power of 5 in the latter. This is so since the largest value for $i$ is $2 j+1$ and the largest exponent $t$ such that $5^{t}$ divides $(2 j+1)$ ! is given by

$$
t=\sum_{i=1}^{\infty}\left\lfloor\frac{2 j+1}{5^{i}}\right\rfloor<\sum_{i=1}^{\infty} \frac{2 j+1}{5^{i}}=\frac{2 j+1}{4}<j
$$

(The above identity can be found in [4]).
Since there is a factor of $5^{r-1}$ in $n-m$ we get the desired divisibility property. Hence only the term corresponding to $j=0$ remains. That is, $n-m \equiv 0\left(\bmod 5^{r}\right)$. Now we can say that $5^{r} \mid n-m$ and $4 \cdot 5^{r-1} \mid n-m$. Thus $4 \cdot 5^{r} \mid n-m$. We know that $0 \leq m, n<4 \cdot 5^{r}$, and so we must conclude that $n=m$.

Therefore any residue mod $5^{r}$ appears at most four times, which implies that each residue must appear exactly four times, which gives us $F\left(\bmod 5^{r}\right)$ is uniform. The induction is complete and the theorem proved.

While $F(\bmod m)$ is uniformly distributed only for $m=5^{e}$, one wonders if there is at least a predictable distribution of residues under different moduli. In 1992 E. T. Jacobson[10] fully described the distribution of residues in $F\left(\bmod 2^{e}\right)$ and $F\left(\bmod 2^{i} \cdot 5^{j}\right)$ for $i \geq 5$, and $j \geq 0$. We present his results below without proof.

Let $v(m, b)$ be the number of occurrences of $b$ as a residue in one period of $F(\bmod m)$. We have seen that $v\left(5^{e}, b\right)=4$ for all $b\left(\bmod 5^{e}\right)$.

Theorem 3.23 For $F\left(\bmod 2^{e}\right)$ the following is true:

For $1 \leq e \leq 4$ :

$$
\begin{aligned}
& v(2,0)=1 \\
& v(2,1)=2 \\
& v(4,0)=v(4,2)=1 \\
& v(8,0)=v(8,2)=v(16,0)=v(16,8)=2 \\
& v(16,2)=4 \\
& v\left(2^{e}, b\right)=1 \text { if } b \equiv 3(\bmod 4) \text { and } 2 \leq e \leq 4 \\
& v\left(2^{e}, b\right)=3 \text { if } b \equiv 1(\bmod 4) \text { and } 2 \leq e \leq 4 \\
& v\left(2^{e}, b\right)=0 \text { in all other cases. }
\end{aligned}
$$

For $e \geq 5$ :

$$
v\left(2^{e}, b\right)=\left\{\begin{array}{l}
1, \text { if } b \equiv 3(\bmod 4) \\
2, \text { if } b \equiv 0(\bmod 8) \\
3, \text { if } b \equiv 1(\bmod 4) \\
8, \text { if } b \equiv 2(\bmod 32) \\
0, \text { for all other residues. }
\end{array}\right.
$$

For $F\left(\bmod 2^{i} \cdot 5^{j}\right)$ where $i \geq 5$, and $j \geq 0$, the following is true:

$$
v\left(2^{i} \cdot 5^{j}, b\right)=\left\{\begin{array}{l}
1, \text { if } b \equiv 3(\bmod 4) \\
2, \text { if } b \equiv 0(\bmod 8) \\
3, \text { if } b \equiv 1(\bmod 4) \\
8, \text { if } b \equiv 2(\bmod 32) \\
0, \text { for all other residues. }
\end{array}\right.
$$

It does not appear that any other work has been published on the distribution of residues for other moduli.

### 3.3 The Zeros Of $F(\bmod m)$

The previous section indicates that the problem of describing all the residues for a given modulus can be quite difficult, but when we restrict our attention to the behavior of the zeros, many fascinating relationships become readily apparent.

Let $\alpha(m)$ denote the subscript of the first positive term of the Fibonacci sequence which is divisible by $m$. Vinson calls this the restricted period of $F(\bmod m)$. Since the subscripts of the terms for which $F_{n} \equiv 0(\bmod m)$ form a simple arithmetic progression, it is clear that $\alpha(m) \mid k(m)$. In fact one sees without too much difficulty that $\alpha(m) \mid n$ if and only if $m \mid F_{n}$. We use this idea in the following theorem.

Theorem 3.24 $\alpha(m) \mid \alpha(m n)$.

Proof: By definition, we know that $m n \mid F_{\alpha(m n)}$. Clearly then $m \mid F_{\alpha(m n)}$, and so $\alpha(m) \mid \alpha(m n)$.

Let $s(m)$ be the least residue of $F_{\alpha(m)+1}$ modulo $m$. Because of the relationship $\left(F_{\alpha(m)}, F_{\alpha(m)+1}\right)=$ $s(m)(0,1)(\bmod m)$ we call $s(m)$ the multiplier of $F(\bmod m)$.

Finally, let $\beta(m)$ denote the order of $s(m)$ modulo $m$. In other words, $s(m)^{\beta(m)} \equiv$ $1(\bmod m)$, and if $n<\beta(m)$ then $s(m)^{n} \not \equiv 1(\bmod m)$.

Note the table in appendix B which compares the values of $m, k(m), \alpha(m)$, and $\beta(m)$. The next theorem ties together these three functions nicely. Robinson[15] states and proves it, but also mentions that is a well known property. The proof presented here is the author's.

Theorem 3.25 $k(m)=\alpha(m) \beta(m)$.

Proof: Suppose that a single period of $F(\bmod m)$ is partitioned into smaller, finite subsequences $A_{0}, A_{1}, A_{2}, \ldots$ as shown below:

$$
\begin{equation*}
\underbrace{01 \cdots s_{1}}_{A_{0}} \underbrace{0 s_{1} \cdots s_{2}}_{A_{1}} \underbrace{0 s_{2} \cdots s_{3}}_{A_{2}} 0 s_{3} \cdots \cdots \cdots \cdot 1 \tag{3.5}
\end{equation*}
$$

Each subsequence $A_{i}$ has $\alpha(m)$ terms, it contains exactly one zero, and $s_{1}=$ $s(m)$.

Every subsequence $A_{i}$ for $i \geq 1$ is a multiple of $A_{0}$. More precisely, the following congruences hold modulo $m$.

$$
\begin{aligned}
& A_{1} \equiv s_{1} A_{0} \\
& A_{2} \equiv s_{2} A_{0} \\
& \vdots \\
& \\
& A_{n-1} \equiv s_{n-1} A_{0} \\
& A_{n} \equiv s_{n} A_{0} \\
& \vdots
\end{aligned}
$$

Now the last term in $A_{n-1}$ is $s_{n}$, and the last term in $A_{0}$ is $s_{1}$. Thus

$$
\begin{aligned}
s_{n} & \equiv\left(s_{n-1}\right) \cdot s_{1} \\
& \equiv\left(s_{n-2}\right) \cdot s_{1} \cdot s_{1} \\
& \equiv\left(s_{n-3}\right) \cdot s_{1} \cdot s_{1} \cdot s_{1} \\
& \vdots \\
& \equiv s_{1}^{n}
\end{aligned}
$$

with congruences modulo $m$. Since $\beta(m)$ is the order of $s_{1}$, sequence (3.5) can be rewritten as

$$
01 \cdots 0 s_{1} \cdots 0 s_{1}^{2} \cdots 0 s_{1}^{3} \cdots \cdots \cdots 0 s_{1}^{\beta(m)-1} \cdots 01
$$

Thus $\beta(m)$ can be interpreted in a different way: it is the number of zeros in a single period of $F(\bmod m)$. Clearly it follows that $k(m)=\alpha(m) \beta(m)$.

There is an identity which follows from the proof.

Identity $3.26 F_{n \cdot \alpha(m)+r} \equiv F_{\alpha(m)+1}^{n} \cdot F_{r}(\bmod m)$.
Proof: The identity comes from the fact that $A_{n} \equiv s_{1}^{n} A_{0}$. More specifically, the $r^{\text {th }}$ term of $A_{n}$ is congruent to $s_{1}^{n}$ times the $r^{\text {th }}$ term of $A_{0}$ modulo $m$.

As a point of interest, note the property that $\operatorname{gcd}\left(m, s_{i}\right)=1$ for all $i$. This must be the case since $\left(s_{i}\right)^{\beta(m)}=\left(s_{1}^{i}\right)^{\beta(m)}=\left(s_{1}^{\beta(m)}\right)^{i} \equiv 1(\bmod m)$. We could also draw this conclusion from theorem 1.1, realizing that if $m \mid F_{n}$ then $m$ and $F_{n+1}$ have no nontrivial divisors in common.

The following theorem doesn't appear to give us any immediate insight into $F(\bmod m)$, but a couple of nice corollaries follow from it. The proof comes from Robinson [15], but he acknowledges that Morgan Wood knew the result in the early 1930's.

Theorem $3.27 k(m)=\operatorname{gcd}(2, \beta(m)) \cdot \operatorname{lcm}[\alpha(m), \gamma(m)]$ where $\gamma(2)=1$ and $\gamma(m)=2$ for $m>2$.

Proof: By identity 1.8, $F_{n}^{2}-F_{n+1} F_{n-1}=(-1)^{n+1}$ so

$$
F_{\alpha(m)}^{2}-F_{\alpha(m)+1} F_{\alpha(m)-1}=(-1)^{\alpha(m)+1}
$$

Since $F_{\alpha(m)} \equiv 0$ and $F_{\alpha(m)+1} \equiv F_{\alpha(m)-1}(\bmod m)$,

$$
-F_{\alpha(m)+1}^{2} \equiv(-1)^{\alpha(m)+1} \quad(\bmod m)
$$

That is,

$$
\begin{equation*}
(s(m))^{2} \equiv(-1)^{\alpha(m)} \quad(\bmod m) \tag{3.6}
\end{equation*}
$$

Thus $(s(m))^{2}$ and $(-1)^{\alpha(m)}$ have the same order modulo $m$. Specifically,

$$
\frac{\beta(m)}{\operatorname{gcd}(2, \beta(m))}=\frac{\gamma(m)}{\operatorname{gcd}(\alpha(m), \gamma(m))}
$$

where $\gamma(m)$ is the order of -1 modulo $m$. Thus

$$
\begin{aligned}
k(m) & =\alpha(m) \beta(m)=\alpha(m) \frac{\operatorname{gcd}(2, \beta(m)) \cdot \gamma(m)}{\operatorname{gcd}(\alpha(m), \gamma(m))} \\
& =\operatorname{gcd}(2, \beta(m)) \cdot \operatorname{lcm}[\alpha(m), \gamma(m)]
\end{aligned}
$$

Corollary $3.28 k(m)$ is even for $m>2$.

Proof: By the proceeding theorem, if $k(m)$ is odd we must have $\operatorname{lcm}[\alpha(m), \gamma(m)]$ odd. For that to happen $\gamma(m)$ must be odd. By the nature of $\gamma(m)$ then $m=2$. Hence the contrapositive (for applicable values of $m$ ): If $m>2$ then $k(m)$ is even.

One of the more surprising properties of $F(\bmod m)$ is demonstrated in the following corollary.

Corollary $3.29 \beta(m)=1$, 2, or 4 .

## Proof:

$$
\begin{aligned}
k(m) & =\operatorname{gcd}(2, \beta(m)) \cdot \operatorname{lcm}[\alpha(m), \gamma(m)] \\
& =(1 \text { or } 2) \cdot(\alpha(m) \text { or } 2 \alpha(m)) \\
& =\alpha(m), 2 \alpha(m), \text { or } 4 \alpha(m) .
\end{aligned}
$$

Therefore $\beta(m)=1,2$, or 4 .

Recall that it is this theorem which allows us to say that $k(m)<m^{2}-1$ for $m \geq 6$.
We have already seen that $\alpha(m)$ shares a property with $k(m)$ in that $\alpha(m) \mid \alpha(m n)$. We will demonstrate that some other properties of $k(m)$ are also exhibited in $\alpha(m)$. Like $k(m)$, Vinson[21] shows we can express $\alpha(m)$ in terms of $\alpha\left(p_{i}^{e_{i}}\right)$ where $m=\prod p_{i}^{e_{i}}$ is the prime factorization of $m$.

Theorem 3.30 If $m$ has the prime factorization $m=\prod p_{i}^{e_{i}}$ then $\alpha(m)=\operatorname{lcm}\left[\alpha\left(p_{i}^{e_{i}}\right)\right]$.

Proof: Notice,

$$
\begin{aligned}
m \mid F_{n} & \Longleftrightarrow p_{i}^{e_{i}} \mid F_{n} \text { for all } i \\
& \Longleftrightarrow \alpha\left(p_{i}^{e_{i}}\right) \mid n \text { for all } i
\end{aligned}
$$

The smallest $n$ which satisfies the last condition, and hence all of them, is $n=$ $\operatorname{lcm}\left[\alpha\left(p_{i}^{e_{i}}\right)\right]$. Thus according to the first condition, $F_{n}$ is the smallest Fibonacci number divisible by $m$. That is, $\alpha(m)=n=\operatorname{lcm}\left[\alpha\left(p_{i}^{e_{i}}\right)\right]$.

Again, like $k(m)$, we can express $\alpha(m)$ in a slightly more convenient form.

Theorem 3.31 $\alpha([m, n])=[\alpha(m), \alpha(n)]$, where brackets denote the least common multiple function.

## Proof:

$$
\begin{aligned}
F_{t} \equiv 0(\bmod [m, n]) & \Longleftrightarrow F_{t} \equiv 0(\bmod m) \text { and } F_{t} \equiv 0(\bmod n) \\
& \Longleftrightarrow \alpha(m) \mid t \text { and } \alpha(n) \mid t
\end{aligned}
$$

The smallest $t$ for which the first condition is true is $t=\alpha([m, n])$. the smallest $t$ for which the last condition is true is $t=[\alpha(m), \alpha(n)]$. The theorem follows.

A third similarity exists: if $p$ is an odd prime and $t$ is the largest integer such that $\alpha\left(p^{t}\right)=\alpha(p)$ then $\alpha\left(p^{e}\right)=p^{e-t} \alpha(p)$. This result exists as a corollary to yet another surprising theorem from [15].

Theorem 3.32 For $p$ any odd prime, $\beta\left(p^{e}\right)=\beta(p)$.

Proof: We again make use of the Fibonacci matrix, $U$. By equation (3.3) we know that

$$
U^{\alpha\left(p^{e+1}\right)} \equiv s\left(p^{e+1}\right) I\left(\bmod p^{e+1}\right)
$$

Furthermore,

$$
U^{\alpha\left(p^{e}\right)} \equiv s\left(p^{e}\right) I\left(\bmod p^{e}\right)
$$

which implies

$$
U^{p \alpha\left(p^{e}\right)} \equiv\left(s\left(p^{e}\right) I+p^{e} B\right)^{p} \equiv\left(s\left(p^{e}\right)\right)^{p} I\left(\bmod p^{e+1}\right)
$$

Hence $\alpha\left(p^{e+1}\right) \mid p \alpha\left(p^{e}\right)$. Since $\alpha(m) \mid \alpha(m n)$ we also know $\alpha\left(p^{e}\right) \mid \alpha\left(p^{e+1}\right)$. Consequently, $\alpha\left(p^{e+1}\right)=\alpha\left(p^{e}\right)$ or $p \alpha\left(p^{e}\right)$. It follows that $\frac{\alpha\left(p^{e}\right)}{\alpha(p)}=p^{i}$ and similarly we can say $\frac{k\left(p^{e}\right)}{k(p)}=p^{j}$. Clearly,

$$
\frac{k\left(p^{e}\right)}{\alpha(p)} \cdot \frac{\alpha\left(p^{e}\right)}{\alpha\left(p^{e}\right)}=\frac{k\left(p^{e}\right)}{\alpha(p)} \cdot \frac{k(p)}{k(p)}
$$

and so

$$
\frac{\alpha\left(p^{e}\right)}{\alpha(p)} \cdot \frac{k\left(p^{e}\right)}{\alpha\left(p^{e}\right)}=\frac{k(p)}{\alpha(p)} \cdot \frac{k\left(p^{e}\right)}{k(p)}
$$

Since $\frac{k\left(p^{e}\right)}{\alpha\left(p^{e}\right)}=\beta\left(p^{e}\right)$ and $\frac{k(p)}{\alpha(p)}=\beta(p)$,

$$
p^{i}(1,2, \text { or } 4)=(1,2, \text { or } 4) p^{j}
$$

Since we assumed $p$ to be odd, we must have $p^{i}=p^{j}$. That is, $\frac{\alpha\left(p^{e}\right)}{\alpha(p)}=\frac{k\left(p^{e}\right)}{k(p)}$ which implies $\frac{k(p)}{\alpha(p)}=\frac{k\left(p^{e}\right)}{\alpha\left(p^{e}\right)}$. In other words, $\beta(p)=\beta\left(p^{e}\right)$.

Corollary 3.33 If $p$ is an odd prime and $t$ is the largest integer such that $\alpha\left(p^{t}\right)=\alpha(p)$ then $\alpha\left(p^{e}\right)=p^{e-t} \alpha(p)$. In fact, this $t$ is also the largest integer such that $k\left(p^{t}\right)=k(p)$.

Proof: This follows directly from the previous proof where $\frac{\alpha\left(p^{e}\right)}{\alpha(p)}=\frac{k\left(p^{e}\right)}{k(p)}$.
The case where $p=2$ exists as a corollary to theorem 3.36.
We will now examine the function $\beta(m)$ more closely. The next three theorems present some useful relationships between $\beta(m), \alpha(m)$, and $k(m)$.

Theorem 3.34 For $m \geq 3, \beta(m)=4$ if and only if $\alpha(m)$ is odd.

Proof: Assume $\beta(m)=4$. Then $(s(m))^{2}$ is the residue after the second zero and by equation (3.6) we know $(s(m))^{2} \equiv(-1)^{\alpha(m)}$. Clearly, $(s(m))^{2} \not \equiv 1$ and so $\alpha(m)$ must be odd.

Assume $\alpha(m)$ is odd. In this case, equation (3.6) tells us that $(s(m))^{2} \equiv-1$. The only possible value for $\beta(m)$ now is 4 .

In order to show some necessary and sufficient conditions for when $\beta(m)=1$, we rely on the identity $F_{k(m)-j} \equiv F_{-j}=(-1)^{j+1} F_{j}(\bmod m)$.

Theorem $3.35 \beta(m)=1$ if and only if $4 \nmid k(m)$.

Proof: We will prove the contrapositive of the theorem in both directions. First, assume that $4 \mid k(m)$. Then if we let $j=\frac{k(m)}{2}+1$ in the identity preceding the theorem, and make note that this $j$ is odd, we get $F_{\frac{k(m)}{2}-1} \equiv F_{\frac{k(m)}{2}+1}(\bmod m)$. By the Fibonacci recurrence relation this implies $F_{\frac{k(m)}{2}} \equiv 0(\bmod m)$, which in turn implies $\beta(m) \neq 1$.

If $\beta(m) \neq 1$ then $\beta(m)=2$ or 4 . We know that $k(m)=\alpha(m) \beta(m)$, so if $\beta(m)=4$ then clearly $4 \mid k(m)$. If $\beta(m)=2$, then by the previous theorem $\alpha(m)$ is even, and once again $4 \mid k(m)$.

Since theorems 3.34 and 3.35 are if and only if, the next theorem appears as a natural consequence.

Theorem $3.36 \beta(m)=2$ if and only if $4 \mid k(m)$ and $\alpha(m)$ is even.

Corollary 3.37 If $4 \mid \alpha(m)$ then $\beta(m)=2$.

Corollary 3.38 If $8 \mid k(m)$ then $\beta(m)=2$.

Corollary $3.39 \beta(2)=\beta(4)=1$. For $e \geq 3, \beta\left(2^{e}\right)=2$.

Proof: By inspection, $\beta(2)=\beta(4)=1$ and $\beta(8)=2$. From theorem 3.5 we know that $k\left(2^{e}\right)=3 \cdot 2^{e-1}$. Since $k(16)=24$ we see $8 \mid k\left(2^{e}\right)$ for $e \geq 4$, and we can apply the preceding corollary.

We must be careful when we try to apply theorem 3.36. We can not conclude that if $\beta(m)=2$ then $4 \mid \alpha(m)$. For example, $\beta(40)=2$, yet $\alpha(40)=30$. However, when the modulus is a prime or a power of a prime, theorem 3.36 can be strengthened. The following theorem found in [21] will be used later.

Theorem 3.40 Let $p$ be an odd prime. If $\beta\left(p^{e}\right)=2$ then $4 \mid \alpha\left(p^{e}\right)$.

Proof: First we show that the theorem is true for $e=1$. When $\beta(p)=2$, theorem 3.34 assures us that $\alpha(p)$ is even. In identity 3.26 , let $n=1$ and $r=-\frac{1}{2} \alpha(p)$ to attain

$$
F_{\frac{1}{2} \alpha(p)} \equiv F_{\alpha(p)+1} F_{-\frac{1}{2} \alpha(p)} \quad(\bmod p)
$$

Noting that $F_{\alpha(p)+1}=s(p)$ and that $s(p)^{2} \equiv(-1)^{\alpha(p)}(\bmod p)$, we can multiply both sides of the above congruence by $F_{\alpha(p)+1}$ and apply identity 1.3 to achieve

$$
F_{\alpha(p)+1} F_{\frac{1}{2} \alpha(p)} \equiv(-1)^{\alpha(p)}(-1)^{\frac{1}{2} \alpha(p)+1} F_{\frac{1}{2} \alpha(p)} \quad(\bmod p) .
$$

We recall that $\alpha(p)$ is even, then multiply both sides by $F_{\frac{1}{2} \alpha(p)}^{p-2}$ and apply Fermat's theorem to get

$$
F_{\alpha(p)+1} \equiv(-1)^{\frac{1}{2} \alpha(p)+1} \quad(\bmod p)
$$

Since $\beta(p)=2$ we know that $F_{\alpha(p)+1} \not \equiv 1$. Thus $(-1)^{\frac{1}{2} \alpha(p)+1}=-1$ which implies $4 \mid \alpha(p)$ and we have proved the theorem for $e=1$.

Since $p$ is odd, $\beta\left(p^{e}\right)=2$ implies that $\beta(p)=2$. We have seen that this implies $4 \mid \alpha(p)$, and so by theorem $3.24,4 \mid \alpha\left(p^{e}\right)$. Thus the theorem is proved.

So far we have been able to find $\beta(m)$ only by analyzing $k(m)$ or $\alpha(m)$. The next theorem gives us a method for finding $\beta([m, n])$ if we know $\beta(m)$ and $\beta(n)$. Vinson does not state this theorem explicitly, but the author was able to construct it from the information given by him.

Theorem 3.41 Given $\beta(m)$ and $\beta(n)$, the table below determines the value of $\beta([m, n])$.
Once again, brackets denote the least common multiple function.
$\underline{\beta([m, n])}$

$$
\beta(n)
$$

Proof: Let

$$
\begin{array}{ccc}
\alpha(m)=2^{r} a & \beta(m)=2^{s} & k(m) 2^{t} a \\
\alpha(n)=2^{w} b & \beta(n)=2^{x} & k(n) 2^{y} b
\end{array}
$$

where $a, b$ are odd integers. Hence

$$
\begin{aligned}
{[k(m), k(n)] } & =2^{\max (t, y)} \cdot[a, b] \\
\text { and } \quad[\alpha(m), \alpha(n)] & =2^{\max (r, w)} \cdot[a, b] .
\end{aligned}
$$

Then

$$
\beta([m, n])=\frac{k([m, n])}{\alpha([m, n])}=\frac{[k(m), k(n)]}{[\alpha(m), \alpha(n)]}=2^{\max (t, y)-\max (r, w)} .
$$

Notice that $r+s=t$ and $w+x=y$. We now address four cases.
Case 1: To describe the diagonal of the table, suppose $\beta(m)=\beta(n)$, that is, $s=x$. Then $\max (t, y)-\max (r, w)=\max (r+s, w+x)-\max (r, w)=s=x$. Hence $\beta([m, n])=2^{s}=2^{x}=\beta(m)=\beta(n)$.

In order to prove the remaining three cases it is helpful to translate theorems 3.35, 3.36, and 3.34 into statements about $r, s$, and $t$ :

$$
\begin{aligned}
\text { If } s=0 \text { then } t= & 0(\text { for } m=2) \text { or } t=1(\text { for } m>2) . \\
& \text { Respectively, } r=0 \text { or } r=1 .
\end{aligned}
$$

If $s=1$ then $t \geq 2$ and $r \geq 1$.
If $s=2$ then $r=0$ and hence, $t=2$.
Analogous statements hold for $w, x$, and $y$.
Case 2: Suppose $\beta(m)=4$ and $\beta(n)=1$, that is, $s=2$ and $x=0$. Since $s=2$ we know that $r=0$ and $t=2$. Also, since $x=0$ we know that either $w=0$ or $w=1$.

Case 2a. Say $x=0, w=0$, and so $y=0$. Then $\max (t, y)-\max (r, w)=$ $2-0=2$. Hence $\beta([m, n])=2^{2}=4$.

Case 2b. Say $x=0, w=1$, and so $y=1$. Then $\max (t, y)-\max (r, w)=$ $2-1=1$. Hence $\beta([m, n])=2^{1}=2$.

Case 3: Suppose $\beta(m)=2$ and $\beta(n)=1$, that is, $s=1$ and $x=0$. Since $s=1$ we know that $t \geq 2$ and $r \geq 1$. Again, since $x=0$ either $w=0$ or $w=1$.

Case 3a. Say $x=0, w=0$, and so $y=0$. Then $\max (t, y)-\max (r, w)=$ $t-r=s=1$. Hence $\beta([m, n])=2^{1}=2$.

Case 3b. Say $x=0, w=1$, and so $y=1$. Then $\max (t, y)-\max (r, w)=$ $t-r=s=1$. Hence $\beta([m, n])=2^{1}=2$.

Case 4: Suppose $\beta(m)=4$ and $\beta(n)=2$, that is, $s=2$ and $x=1$. Then $r=0, t=2$, and $w \geq 1, y \geq 2$. Then $\max (t, y)-\max (r, w)=y-w=x=1$. Hence $\beta([m, n])=2^{1}=2$.

This completes the proof.

There are two interesting corollaries that follow.

Corollary 3.42 If $3 \mid m$ then $\beta(m)=2$.

Proof: Since $\beta(3)=2$ we know that $\beta\left(3^{e}\right)=2$. Let $m$ be expressed as $3^{e} n$ where $3 \nmid n$. By the previous theorem, then $\beta(m)=\beta\left(\left[3^{e}, n\right]\right)=2$.

Corollary $3.43 \beta(m)=1$ if and only if $8 \nmid m$ and $\alpha(p) \equiv 2(\bmod 4)$ for all odd primes $p$ that divide $m$.

Proof: Let $m$ have the prime factorization $m=\prod p_{i}^{e_{i}}$. Suppose $\beta(m)=1$. By theorem 3.41 it is easy to see that we must have $\beta\left(p_{i}^{e_{i}}\right)=1$ for all $i$. If $p_{1}$ is the smallest prime in the prime factorization of $m$ and $p_{1}=2$ then by corollary 3.39, $e_{1} \leq 2$ and thus $8 \nmid m$. Recall that for odd $p, \beta\left(p_{i}^{e_{i}}\right)=\beta\left(p_{i}\right)$. Theorem 3.36 tells us that if $\alpha\left(p_{i}\right) \equiv 1$ or $3(\bmod 4)$ then $\beta\left(p_{i}\right)=4$. Theorem 3.34 tells us that if $\alpha\left(p_{i}\right) \equiv 0(\bmod 4)$ then $\beta\left(p_{i}\right)=4$. Hence when $\beta(m)=1$ we must have $\alpha\left(p_{i}\right) \equiv 2(\bmod 4)$ for all $i$.

Suppose that $8 \nmid m$. Thus if $2^{e}$ is a factor of $m$, then $e \leq 2$ and $\beta\left(2^{e}\right)=1$. For odd $p$, if $\alpha(p) \equiv 2(\bmod 4)$ then $\beta(p)=1$ by theorems 3.35 and 3.40. Hence if we suppose that $\alpha\left(p_{i}^{e_{i}}\right) \equiv 2(\bmod 4)$ for all $i$ we have $\beta\left(p_{i}^{e_{i}}\right)=1$ for all $i$ and then theorem 3.41 indicates that $\beta(m)=1$.

We now know that for composite $m, \beta(m)$ can be determined by factoring $m$ into smaller moduli. We also know that for odd primes $p, \beta\left(p^{e}\right)=\beta(p)$. Can we determine $\beta(p)$ for odd primes $p$ ? While $k(p)$ and $\alpha(p)$ have strongly resisted this analysis, we can make some progress on $\beta(p)$. The four results are grouped together in the following theorem found in [21].

Theorem 3.44 For odd primes $p$,

> (i) $\quad$ If $p \equiv 11$ or $19(\bmod 20)$ then $\beta\left(p^{e}\right)=1$.
> (ii) $\quad$ If $p \equiv 3$ or $7(\bmod 20)$ then $\beta\left(p^{e}\right)=2$.
> (iii) $\quad$ If $p \equiv 13$ or $17(\bmod 20)$ then $\beta\left(p^{e}\right)=4$.
> (iv) $\quad$ If $p \equiv 21$ or $29(\bmod 40)$ then $\beta\left(p^{e}\right) \neq 2$.

Proof: Since we are assuming $p$ odd, we need only prove each part for $e=1$ and the conclusion will follow. Before looking at the individual cases we take some time to develop a couple useful facts. First, since $\beta(p)$ is the order of $s(p)$, we know that $(s(p))^{\beta(p)} \equiv 1(\bmod p)$. In addition, we know by Fermat's theorem that $(s(p))^{p-1} \equiv 1(\bmod p)$. Thus $\beta(p) \mid p-1$ and it follows that if $p \equiv 3(\bmod 4)$ then $\beta(p) \neq 4$.

Secondly, if $p=5 t \pm 2$ then $F_{p} \equiv-1$ and $F_{p+1} \equiv 0(\bmod p)$. We see that $\alpha(p) \mid p+1$ but $k(p) \nmid p+1$. Hence $\alpha(p) \neq k(p)$ and consequently $\beta(p) \neq 1$. Now we turn our attention to the four results.
(i) Here $p \equiv 3(\bmod 4)$, so $\beta(p) \neq 4$. Assume $\beta(p)=2$. Then by theorem 3.36, $4 \mid k(p)$. Since $p=5 t \pm 1$ we have $k(p) \mid p-1$, and so $4 \mid p-1$. However, this is a contradiction since $p-1 \equiv 10$ or $18(\bmod 20)$. Thus $\beta(p)=1$.
(ii) Again, $p \equiv 3(\bmod 4)$, so $\beta(p) \neq 4$. Now $p=5 t \pm 2$ and we have seen that this implies $\beta(p) \neq 1$. Thus $\beta(p)=2$.
(iii) As in the previous part, $p=5 t \pm 2$ and so $\beta(p) \neq 1$. Also, we know $\alpha(p) \mid p+1$. In this case $p \equiv 1(\bmod 4)$ so $4 \nmid p+1$. Hence $4 \nmid \alpha(p)$. Applying theorem 3.40 we have $\beta(p) \neq 2$. Hence $\beta(p)=4$.
(iv) Suppose $\beta(p)=2$. By theorem 3.40, $4 \mid \alpha(p)$ and so consequently $8 \mid k(p)$. Furthermore, since $p=5 t \pm 1$, theorem 3.12 assures us that $k(p) \mid p-1$. It follows that $8 \mid p-1$. However, $p-1 \equiv 20$ or $28(\bmod 40)$ so clearly $8 \nmid p-1$. Thus we have our contradiction and we can say $\beta(p) \neq 2$.

We would like to know if anything can be said about the primes not covered by the theorem, namely $p \equiv 1$ or $9(\bmod 40)$. Also, can we be more exact about primes where $p \equiv 21$ or $29(\bmod 40) ?$ Vinson provides the following examples to show that his theorem
is "complete":

$$
\begin{aligned}
& \text { For } p \equiv \quad 1(\bmod 40): \quad \beta(521)=1, \quad \beta(41)=2, \quad \beta(761)=4 \\
& \text { For } p \equiv \quad 9(\bmod 40): \quad \beta(809)=1, \quad \beta(409)=2, \quad \beta(89)=4 \\
& \text { For } p \equiv 21(\bmod 40): \quad \beta(101)=1, \quad \beta(61)=4 \\
& \text { For } p \equiv 29(\bmod 40): \quad \beta(29)=1, \quad \beta(109)=4
\end{aligned}
$$

We finish section 3.3 with a couple of theorems promised at the end of section 3.1. While they speak to the character of the period, their proofs are made easy by the theory developed in this section.

Theorem 3.45 (i) If $n \geq 5$ is odd then $k\left(F_{n}\right)=4 n$.
(ii) If $n \geq 4$ is even then $k\left(F_{n}\right)=2 n$.

Proof: We first note that if $F_{n}$ is used for the modulus, then naturally $\alpha\left(F_{n}\right)=$ $n$.
(i) This result follows from the fact that for $m \geq 3, \alpha(m)$ odd implies $\beta(m)=$ 4. For $n \geq 5$ and odd, $F_{n} \geq 3$ and $\alpha\left(F_{n}\right)=n$ is odd. Thus $k\left(F_{n}\right)=4 n$.
(ii) Here, $\alpha\left(F_{n}\right)=n$ is even so $\beta\left(F_{n}\right)=1$ or 2 . If $\beta\left(F_{n}\right)=1$ then $F_{n-1} \equiv$ $F_{n+1} \equiv 1\left(\bmod F_{n}\right)$. However, $F_{1}, F_{2}, F_{3}, \ldots, F_{n-1}$ is non decreasing and $F_{3} \equiv$ $2\left(\bmod F_{n}\right)$, hence our contradiction. Therefore, $\beta\left(F_{n}\right)=2$ and $k\left(F_{n}\right)=2 n$.

Theorem 3.46 (i) If $n \geq 3$ is odd then $k\left(L_{n}\right)=2 n$.
(ii) If $n \geq 2$ is even then $k\left(L_{n}\right)=4 n$.

Proof: First we establish that $\alpha\left(L_{n}\right)=2 n$. From identity 1.10, $F_{n} L_{n}=F_{2 n}$ which implies $F_{2 n} \equiv 0\left(\bmod L_{n}\right)$ so certainly $\alpha\left(L_{n}\right) \mid 2 n$. Now if $\alpha\left(L_{n}\right) \neq 2 n$ then $\alpha\left(L_{n}\right) \leq n$. In other words, $L_{n} \mid F_{t}$ for some $t \leq n$. However, $L_{n}>F_{t}$ for $2 \leq t \leq n$, so clearly $L_{n} \nmid F_{t}$. Hence $\alpha\left(L_{n}\right)=2 n$.
(i)

$$
\begin{aligned}
F_{n+1} L_{n} & =F_{n+1}\left(F_{n+1}+F_{n-1}\right) \\
& =F_{n+1}^{2}+F_{n+1} F_{n-1} \\
& =F_{n+1}^{2}+F_{n}^{2}+(-1)^{n}(\text { by identity } 1.8) \\
& =F_{2 n+1}-1(\text { by identity } 1.7 \text { and } n \text { odd })
\end{aligned}
$$

Thus $F_{2 n+1} \equiv 1\left(\bmod L_{n}\right)$ and we can say $\beta\left(L_{n}\right)=1$. Therefore $k\left(L_{n}\right)=$ $\alpha\left(L_{n}\right)=2 n$.
(ii) When $n$ is even, $4 \mid \alpha\left(L_{n}\right)$ and so by corollary $3.37, \beta\left(L_{n}\right)=2$. Hence $k\left(L_{n}\right)=\alpha\left(L_{n}\right) \cdot 2=4 n$.

## Chapter 4

## Personal Findings

During my survey of known Fibonacci properties I was fortunate enough to stumble across a few areas where apparently very little research had been done. Upon examining these areas more closely I was able to discover yet more astounding properties of the Fibonacci sequence.

### 4.1 Spirolaterals And The Fibonacci Sequence

Spirolaterals, invented in 1973 by Frank C. Odds, are simple graphical representations of finite integer sequences. The rules for creating a spirolateral from a given sequence are simple, and the spirolateral can easily be drawn on a sheet of ordinary graph paper. Suppose we have a sequence $x_{1}, x_{2}, x_{3}, \ldots, x_{n}$. To create the spirolateral draw a line from left to right $x_{1}$ units long, turn right $90^{\circ}$, draw a line $x_{2}$ units long, turn right $90^{\circ}$ and continue in this manner. When the end of the sequence has been reached, start over again with $x_{1}$.

Figure 4.1: Some simple spirolaterals. The circle indicates the starting point.

Eventually, either the line will return to its starting point heading in the initial direction, or else the pattern will wander off the page. It is known that when $n \equiv 1$ or $3(\bmod 4)$ then the spirolateral exhibits 4 -fold symmetry. When $n \equiv 2(\bmod 4)$ then then spirolateral exhibits 2-fold symmetry, and when $n \equiv 0(\bmod 4)$ the spirolateral does not exhibit symmetry and usually glides off the page in some diagonal direction.

I wrote a short computer program that randomly generated sequences and then drew
them as spirolaterals. After playing with the spirolateral program for a while, viewing hundreds of spirolaterals, I was accustomed to seeing interesting symmetries and curious patterns fly off the screen at some diagonal. Then, when I used a period of residues of the Fibonacci sequence under various moduli to generate spirolaterals I was surprised that typically the results were not symmetric and often did not translate off the screen.

Figure 4.2: Some spirolaterals using Fibonacci residues. Here, $F(\bmod 5)$ and $F(\bmod 8)$ are both asymmetric and nontranslating. Circles indicate starting points.

Apparently, after only one time through the period, the line had returned to the starting point and was heading in the initial direction. That is, the sum of the lines drawn to the right equaled the sum of the lines drawn to the left, and the sum of the lines drawn up equaled the sum of the lines drawn down. This seemed a fairly remarkable occurrence, for it indicated a truth about the alternating sum of the residues themselves. After studying many examples, a conjecture was made and eventually a proof was given showing when the alternating sum will be zero.

In order to express clearly the idea of working with the residues themselves, let us introduce some notation. Let $f_{n}$ represent the least nonnegative residue of $F_{n}$ modulo $m$. As we would expect, $f_{n}=f_{n+r \cdot k(m)}$ for any integer $r$. When $n$ is odd, $F_{-n}=F_{n}$ and so $f_{-n}=f_{n}$. When $n$ is even, $F_{-n}=-F_{n}$ which implies $F_{-n}+F_{n} \equiv 0(\bmod m)$ and so either $f_{-n}=f_{n}=0$ or else $f_{-n}+f_{n}=m$

Theorem $4.14 \mid k(m)$ if and only if

$$
\sum_{i=0}^{\frac{k(m)}{2}-1}(-1)^{i} f_{2 i+1}=0
$$

Proof: Let $k=k(m)$ and rewrite the above summation as

$$
\begin{aligned}
& f_{1}-f_{3}+f_{5}-\cdots-f_{k-5}+f_{k-3}-f_{k-1} \\
= & \left(f_{1}-f_{k-1}\right)-\left(f_{3}-f_{k-3}\right)+\cdots-\left(f_{\frac{k}{2}-1}-f_{\frac{k}{2}+1}\right) .
\end{aligned}
$$

First suppose that $4 \mid k$. When $n$ is odd $f_{n}=f_{-n}=f_{k-n}$. Hence each term in parentheses equals zero, implying the entire summation equals zero.

On the other hand, since $f_{n}=f_{k-n}$ for odd $n$ we know that each parenthesized term must equal zero, and in particular $f_{\frac{k}{2}-1}=f_{\frac{k}{2}+1}$. By the recurrence relation we know then $f_{\frac{k}{2}}=0$. Clearly now $\beta(m) \neq 1$ and by theorem 3.35 we can say $4 \mid k$.

It turns out that the same conditions do not ensure that the alternating sum of the evenly subscripted residues will be zero. However, the conditions needed in this case are not very different. First, though, we need a lemma.

Lemma 4.2 Suppose $4 \mid k(m)$ for some $m$ and let $j$ be even. If $j$ is a multiple of $\frac{k(m)}{2}$ then $f_{j}=f_{k-j}=0$ otherwise $f_{j}+f_{k-j}=m$.

Proof: Let $k=k(m)$ and take all congruences $(\bmod m)$. When $j$ is even $F_{k-j} \equiv(-1)^{j+1} F_{j} \equiv-F_{j}$. Thus if $F_{j} \not \equiv 0$ then $f_{j}+f_{k-j}=m$. Since $4 \mid k$ we know by theorem 3.35 that $F_{\frac{k}{2}} \equiv 0$ and consequently if $j$ is a multiple of $\frac{k}{2}$ then $f_{j}=0$. Also, $k-j$ will be a multiple of $\frac{k}{2}$ so $f_{k-j}=0$. Suppose $F_{t} \equiv 0$ for some $0<t<\frac{k}{2}$. Then $\beta(m)=4$ and $\alpha(m)=t$ is necessarily odd. Thus the only time $F_{j} \equiv 0$ and $j$ is even is when $j$ is a multiple of $\frac{k}{2}$. The lemma follows.

Theorem 4.3 If $k(m) \equiv 4(\bmod 8)$ then

$$
\sum_{i=0}^{\frac{k(m)}{2}-1}(-1)^{i} f_{2 i}=0
$$

Proof: The summation above is

$$
\begin{aligned}
& f_{0}-f_{2}+f_{4}-f_{6}+\cdots+f_{k-4}-f_{k-2} \\
= & f_{0}-\left(f_{2}+f_{k-2}\right)+\left(f_{4}+f_{k-4}\right)-\cdots-\left(f_{\frac{k}{2}-2}+f_{\frac{k}{2}+2}\right)+f_{\frac{k}{2}} .
\end{aligned}
$$

By our lemma $f_{0}=f_{\frac{k}{2}}=0$ and each quantity in parentheses equals $m$. There are $\frac{1}{2}\left(\frac{k}{2}-2\right)=\frac{k}{4}-1$ parenthesized terms and since $k \equiv 4(\bmod 8)$ we know $\frac{k}{4}-1$ is even. Hence the entire summation is zero.

We can extend our idea of the spirolateral and instead of restricting ourselves to just $90^{\circ}$ turns we can make spirolaterals with $60^{\circ}$ turns or $45^{\circ}$ etc... If $60^{\circ}$ turns are used, hexagonal type patterns emerge. Occasionally these pattern will return to their starting place when $F(\bmod m)$ for some $m$ is used as the generating sequence. Since every third line is parallel in these pictures, this result indicates that the alternating sum of every third term in these sequences is zero, regardless of where we start to take our sum. The following conjecture expresses this notion.

Conjecture 4.4 If $k(m) \equiv 12(\bmod 24)$ and $\beta(m)=4$ for some $m$, then

$$
\sum_{i=0}^{k(m) / 3-1}(-1)^{i} f_{3 i+j}=0
$$

for $j=0,1,2$.

After only a cursory investigation it appears that this conjecture may yield to a proof if given a couple hours of thought. Also, many times the alternating sum of every fourth, fifth, and so on, residue in a period equals zero. This area seems to be quite open for research.

After trying for a while to find results pertaining to the summation of the residues themselves I turned to a related question. If I take the sum (or alternating sum) of every $n^{\text {th }}$ term of the Fibonacci sequence within a period of $F(\bmod m)$, what will the result be, modulo $m$ ? For example, $k(5)=20$, so what is the sum modulo 5 of every fourth term starting with, say, $F_{2}$ ? Or what can I expect of $F_{3}-F_{8}+F_{13}-F_{18}(\bmod 5)$ ? To this end the following two identities are vital. The following identity is due to Siler[16].

Identity 4.5 For $0 \leq j<n$ and $t \geq 0$, we have

$$
\sum_{i=0}^{t} F_{n i+j}=\frac{F_{n t+n+j}-F_{j}+(-1)^{j+1} F_{n-j}+(-1)^{n+1} F_{n t+j}}{L_{n}-1+(-1)^{n+1}}
$$

Proof: The identity $\sigma \tau=-1$ will be used several times in the proof.

$$
\sum_{i=0}^{t} F_{n i+j}=\sum_{i=0}^{t} \frac{1}{\sqrt{5}}\left(\tau^{n i+j}-\sigma^{n i+j}\right)
$$

$$
\begin{aligned}
& =\frac{1}{\sqrt{5}}\left[\tau^{j} \sum_{i=0}^{t}\left(\tau^{n}\right)^{i}-\sigma^{j} \sum_{i=0}^{t}\left(\sigma^{n}\right)^{i}\right] \\
& =\frac{1}{\sqrt{5}}\left[\frac{\tau^{j}\left(1-\left(\tau^{n}\right)^{t+1}\right)}{1-\tau^{n}}-\frac{\sigma^{j}\left(1-\left(\sigma^{n}\right)^{t+1}\right)}{1-\sigma^{n}}\right] \\
& =\frac{1}{\sqrt{5}}\left[\frac{\tau^{j}\left(1-\sigma^{n}\right)-\tau^{n t+n+j}\left(1-\sigma^{n}\right)-\sigma^{j}\left(1-\tau^{n}\right)+\sigma^{n t+n+j}\left(1-\tau^{n}\right)}{\left(1-\tau^{n}\right)\left(1-\sigma^{n}\right)}\right] \\
& =\frac{1}{\sqrt{5}}\left[\frac{\left(\tau^{j}-\sigma^{j}\right)+(-1)^{j}\left(\tau^{n-j}-\sigma^{n-j}\right)-\left(\tau^{n t+n+j}-\sigma^{n t+n+j}\right)+(-1)^{n}\left(\tau^{n t+j}-\sigma^{n t+j}\right)}{1+(\tau \sigma)^{n}-\left(\tau^{n}+\sigma^{n}\right)}\right] \\
& =\frac{F_{j}+(-1)^{j} F_{n-j}-F_{n t+n+j}+(-1)^{n} F_{n t+j}}{1+(-1)^{n}-L_{n}} .
\end{aligned}
$$

By multiplying the numerator and denominator by -1 we obtain the identity.

The second identity is similar, but concerns alternating sums. I have been unable to find this identity published anywhere, and the proof below is due to Fredric Howard.

Identity 4.6 For $0 \leq j<n$ and $t \geq 0$, we have

$$
\sum_{i=0}^{t}(-1)^{i} F_{n i+j}=\frac{F_{j}+(-1)^{j+1} F_{n-j}+(-1)^{t} F_{n t+n+j}+(-1)^{t+n} F_{n t+j}}{1+(-1)^{n}+L_{n}}
$$

## Proof:

$$
\begin{aligned}
& \qquad \sum_{i=0}^{t}(-1)^{i} F_{n i+j}=\sum_{i=0}^{t} \frac{(-1)^{i}}{\sqrt{5}}\left(\tau^{n i+j}-\sigma^{n i+j}\right) \\
& =\frac{1}{\sqrt{5}}\left[\tau^{j} \sum_{i=0}^{t}\left(-\tau^{n}\right)^{i}-\sigma^{j} \sum_{i=0}^{t}\left(-\sigma^{n}\right)^{i}\right] \\
& =\frac{1}{\sqrt{5}}\left[\frac{\tau^{j}\left(1-\left(-\tau^{n}\right)^{t+1}\right)}{1-\left(-\tau^{n}\right)}-\frac{\sigma^{j}\left(1-\left(-\sigma^{n}\right)^{t+1}\right)}{1-\left(-\sigma^{n}\right)}\right] \\
& =\frac{1}{\sqrt{5}}\left[\frac{\tau^{j}\left(1+\sigma^{n}\right)+(-1)^{t} \tau^{n t+n+j}\left(1+\sigma^{n}\right)-\sigma^{j}\left(1+\tau^{n}\right)-(-1)^{t} \sigma^{n t+n+j}\left(1+\tau^{n}\right)}{\left(1+\tau^{n}\right)\left(1+\sigma^{n}\right)}\right]
\end{aligned}
$$

$$
\left.\begin{array}{l}
=\frac{1}{\sqrt{5}}\left[\frac{\left(\tau^{j}-\sigma^{j}\right)+(-1)^{j+1}\left(\tau^{n-j}-\sigma^{n-j}\right)+}{(-1)^{t}\left(\tau^{n t+n+j}-\sigma^{n t+n+j}\right)+(-1)^{t+n}\left(\tau^{n t+j}-\sigma^{n t+j}\right)}\right. \\
1+(\tau \sigma)^{n}+\left(\tau^{n}+\sigma^{n}\right)
\end{array}\right]
$$

If we fix $n$ and $j$ and sum up (using either identity) all terms of the form $F_{n i+j}$ within a single period of the Fibonacci sequence ( $F_{0} \leq F_{n i+j}<F_{k(m)}$ ) what will the result be? In particular, for what values of $n, j$, and $m$ will the sum be congruent to zero modulo $m$ ?

We will only consider those $n$ such that $n \mid k(m)$. We are not especially interested in looking at, say, every seventh term if the period is not a multiple of seven. When $t=\frac{k(m)}{n}-1$ let $S_{n}^{+}$denote the summation of identity 4.5 and let $S_{n}^{+/-}$denote the alternating summation of identity 4.6.

Hence, letting $k=k(m)$,

$$
S_{n}^{+}=\sum_{i=0}^{\frac{k}{n}-1} F_{n i+j}=\frac{F_{k+j}-F_{j}+(-1)^{j+1} F_{n-j}+(-1)^{n+1} F_{k-n+j}}{L_{n}-1+(-1)^{n+1}} .
$$

Since $F_{j} \equiv F_{k+j}(\bmod m)$,

$$
\begin{aligned}
S_{n}^{+}\left(L_{n}-1+(-1)^{n+1}\right) & \equiv(-1)^{j+1} F_{n-j}+(-1)^{n+1} F_{k-(n-j)} \\
& \equiv(-1)^{j+1} F_{n-j}+(-1)^{n+1+(n-j)+1} F_{n-j} \\
& \equiv 0 \quad(\bmod m)
\end{aligned}
$$

Quite surprisingly, $j$ has dropped out of our equation and the following is then true for all $j$ :

Theorem 4.7 If $\operatorname{gcd}\left(m, L_{n}-1+(-1)^{n+1}\right)=1$ then $S_{n}^{+} \equiv 0(\bmod m)$.

We will now look at some examples to demonstrate the surprising results this theorem gives us.

When $n=1, L_{n}-1+(-1)^{n+1}=1$, and so for any modulus $m, S_{1}^{+} \equiv 0(\bmod m)$. In other words, $F_{0}+F_{1}+F_{2}+\cdots+F_{k(m)-1} \equiv 0(\bmod m)$ for all $m$.

When $n=2, L_{n}-1+(-1)^{n+1}=1$, and so for any modulus $m, S_{2}^{+} \equiv 0(\bmod m)$.
Consider $n=4$. Here $L_{n}-1+(-1)^{n+1}=5$. Thus if $4 \mid k(m)$ but $5 \wedge m$ then $S_{4}^{+} \equiv 0(\bmod m)$. Recall that this means $\sum_{i=0}^{k / 4-1} F_{4 i} \equiv \sum_{i=0}^{k / 4-1} F_{4 i+1} \equiv \sum_{i=0}^{k / 4-1} F_{4 i+2} \equiv$
$\sum_{i=0}^{k / 4-1} F_{4 i+3} \equiv 0(\bmod m)$. Again, it does seem remarkable that the point where we start to take every fourth term does not matter at all. Finding some values for $m$ which satisfy the above conditions is easy to do. By inspection we look for an $m$ such that $4 \mid k(m)$ then using the fact that $k(m) \mid k(m r)$ we let $r$ be any integer except multiples of 5 . We see $k(3)=8$ so some viable choices for $m$ are $3,6,9,12,18,21,24,27,33, \ldots$ Notice the omission of 15 and 30 . Of course, these aren't the only possible values for $m$. We find $k(7)=16$, so 7,14 , $21,28,42, \ldots$ are all valid choices as well. Amazingly, for all these values of $m$ (and many more $), S_{4}^{+} \equiv 0(\bmod m)$.

Next we fix $m=17$ and find all $n$ such that $S_{n}^{+} \equiv 0(\bmod 17)$. Now $k(17)=36$ so we will only consider those $n$ which divide 36 . It just happens that $\operatorname{gcd}\left(17, L_{n}-1+(-1)^{n+1}\right)=1$ for all those $n$ and so $S_{n}^{+} \equiv 0(\bmod 17)$ for $n=1,2,3,4,6,9,12$, and 18. Truly amazing!

When $m=9, k(m)=24$. We find that $\operatorname{gcd}\left(9, L_{n}-1+(-1)^{n+1}\right)=1$ for all divisors, $n$, of 24 except $n=8$. Hence $S_{n}^{+} \equiv 0(\bmod 9)$ for $n=1,2,3,4,6$, and 12 .

It should be noted that we need not always use the first $k(m)$ terms of the Fibonacci sequence in our summations. This comes from the fact that we are summing over a single period of the Fibonacci sequence and the value of $j$ in identities 4.5 and 4.6 is inconsequential. Considering the last example, we can take any 24 consecutive Fibonacci numbers, then add up, say, every third, and our total will continue to be a multiple of 9 .

Now we turn our attention to the alternating sum, $S_{n}^{+/-}$. Again we want $\frac{k(m)}{n}$ to be an integer, but two cases arise: $\frac{k(m)}{n}$ is either even or odd. The case where $\frac{k(m)}{n}$ is even is explored here. In this case the number of positive terms in the summation is the same as the number of negative terms. The case where $\frac{k(m)}{n}$ is odd does not appear to give nice results (probably because it lacks the "symmetry" of the first case) and has not been explored a great deal.

As before, we will now try to find out when $S_{n}^{+/-} \equiv 0(\bmod m)$. Let $k=k(m)$. By identity 4.6 :

$$
S_{n}^{+/-}=\sum_{i=0}^{\frac{k}{n}-1}(-1)^{i} F_{n i+j}=\frac{F_{j}+(-1)^{j+1} F_{n-j}+(-1)^{\frac{k}{n}-1} F_{k+j}+(-1)^{\frac{k}{n}-1+n} F_{k-n+j}}{L_{n}+1+(-1)^{n}}
$$

Assuming $\frac{k}{n}$ is even, and noting $F_{j} \equiv F_{k+j}(\bmod m)$,

$$
S_{n}^{+/-}\left(L_{n}+1+(-1)^{n}\right) \equiv(-1)^{j+1} F_{n-j}+(-1)^{\frac{k}{n}-1+n}(-1)^{n-j+1} F_{n-j}
$$

$$
\begin{aligned}
& \equiv(-1)^{j+1} F_{n-j}+(-1)^{j} F_{n-j} \\
& \equiv 0 \quad(\bmod m)
\end{aligned}
$$

Once again $j$ has dropped out and we are left with the following result.
Theorem 4.8 If $\frac{k(m)}{n}$ is even and $\operatorname{gcd}\left(m, L_{n}+1+(-1)^{n}\right)=1$ then $S_{n}^{+/-} \equiv 0(\bmod m)$.
Here are a couple examples of the application of this theorem.
Let $n=4$. Then $L_{n}+1+(-1)^{n}=9$. Now we want the values for $m$ such that $\frac{k(m)}{4}$ is even and $\operatorname{gcd}(m, 9)=1$, the latter requirement being the same as $3 \Lambda m$. After some inspection we find $m=7$ works since $k(m)=16$. Thus $m=7,14,28,35,49, \ldots$ are all acceptable values. Also, $k(16)=24$ so $m=16,32,64,80,112, \ldots$ work as well. For all these values of $m, S_{4}^{+/-} \equiv 0(\bmod m)$.

When $m=9, k(m)=24$. We see that $\frac{k(m)}{n}$ is even for $n=1,2,3,4,6,12$. Of these values, $\operatorname{gcd}\left(9, L_{n}+1+(-1)^{n}\right)=1$ for $n=1,2,3,6$. Hence $S_{1}^{+/-} \equiv S_{2}^{+/-} \equiv S_{3}^{+/-} \equiv S_{6}^{+/-} \equiv$ $0(\bmod 9)$.

When $m=17, k(m)=36$. Now $\frac{k(m)}{n}$ is even for $n=1,2,3,6,9,18$. Of these values, $\operatorname{gcd}\left(17, L_{n}+1+(-1)^{n}\right)=1$ for $n=1,2,3,6,9$. Hence $S_{1}^{+/-} \equiv S_{2}^{+/-} \equiv S_{3}^{+/-} \equiv S_{6}^{+/-} \equiv$ $S_{9}^{+/-} \equiv 0(\bmod 17)$.

It is remarkable that in the example above where $m=9$, the alternating sum of the residues themselves for $n=1,2,3$, and 6 actually equals zero when $j \neq 0$. When $j=0$, the alternating sum of the residues equals -9 for all four values of $n$.

Similarly, in the example when $m=17$, the alternating sum of the residues themselves actually equals zero for all $j$. Clearly this is an area that is wide open for research and appears to have some fascinating results.

Though we have provided some sufficient conditions indicating when a sum will be congruent to zero, these conditions are nowhere close to necessary. There are many times when a sum will be congruent to zero for some $j$ but not all. It appears that with some work, new and more general sufficient conditions may be found.

The notion of summing Fibonacci numbers over a single period is not new and has been examined previously by Aydin and Smith in [3]. Their approach, however, was to take the sum of powers of all the Fibonacci numbers in a period of $F(\bmod p)$ and observe its value

|  | $\sum F_{i} \equiv 0$ $\sum(-1)^{i} F_{i} \equiv 0$ <br> For all primes $p$ $\sum_{i} F_{i}^{2} \equiv 0$ <br>  $\sum F_{i}^{3} \equiv 0$ | $\sum(-1)^{i} F_{i}^{3} \equiv 0$ |
| :--- | :--- | :--- |
| For $p \neq 3$ |  | $\sum(-1)^{i} F_{i}^{4} \equiv 0$ |
| For $p \neq 11$ | $\sum F_{i}^{5} \equiv 0$ | $\sum(-1)^{i} F_{i}^{5} \equiv 0$ |
| For $p \neq 11,29$ | $\sum F_{i}^{6} \equiv 0$ |  |
|  | $\sum F_{i}^{7} \equiv 0$ | $\sum(-1)^{i} F_{i}^{7} \equiv 0$ |

Table 4.1: Some sums of powers of Fibonacci numbers.
modulo $p$, where $p$ is a prime. Table 4.1 displays a few of their results. All sums are taken over a single period and all congruences are $(\bmod p)$.

It seems that the next step is to look at summations of the form $\sum F_{n i+j}^{e}$ and $\sum(-1)^{i} F_{n i+j}^{e}$. While no known work has been done in this area, empirical evidence suggests that there are many interesting theorems waiting to be proven.

### 4.2 Fibonacci Subsequences

During my research I came across a paper [8] by Herta Freitag in which she describes a property of the unit digits of the Fibonacci numbers. In the paper she examines several subsequences of $F(\bmod 10)$ where the terms of the subsequence actually follow the usual Fibonacci recurrence relation. First she conjectures and proves that $F_{n}+F_{n+5} \equiv$ $F_{n+10}(\bmod 10)$ for all $n$, then she shows that if $j \in\{1,5,13,17,25,29,37,41,49,53\}$ the relation $F_{n}+F_{n+j} \equiv F_{n+2 j}(\bmod 10)$ still holds for all $n$.

Her paper leaves many questions open. Are there other subsequences of this type in $F(\bmod 10)$ which $d o$ depend on the value of $n$ as defined above? What can we say about the subsequences of $F(\bmod m)$ for arbitrary $m$ ? We can immediately answer the first question by noting that $F_{0}, F_{9}, F_{18}, \ldots(\bmod 10)$ forms such a sequence, but $F_{1}, F_{10}, F_{19}, \ldots(\bmod 10)$ does not. We will examine the second question closely.

First we need some notation. If a subsequence $H$ of $F(\bmod m)$ exhibits the recurrence
relation $H_{n+2} \equiv H_{n+1}+H_{n}(\bmod m)$, let us call $H$ a "Fibonacci subsequence modulo $m$ ". We will drop the "modulo $m$ " when the modulus is understood. We will only consider subsequences whose terms are evenly spaced throughout $F(\bmod m)$ and we will denote such subsequence by $\left\{F_{n}, F_{n+j}\right\}$ where $F_{n}$ and $F_{n+j}$ are successive term of the subsequence. We will often use the variables $n$ and $j$ like this where $F_{n}$ is a term in the subsequence and $j$ is the "spread" of the subsequence. Since $F(\bmod m)$ has period $k(m)$, we will always assume $0 \leq n<k(m)$ and $1 \leq j \leq k(m)$.

Let us examine some properties of these Fibonacci subsequences. Let $d=$ $\operatorname{gcd}(j, k(m))$. If $\left\{F_{n}, F_{n+j}\right\}$ is a Fibonacci subsequence then $\left\{F_{n+d x}, F_{n+d x+j}\right\}$ is also a Fibonacci subsequence for all $x$. To see this, consider a period of $F(\bmod m)$ where we start at $F_{n}$ then take every $j^{\text {th }}$ term. When we reach the end of the period, we "loop" back to the start and continue. After "wrapping" around once or several times we will eventually return to $F_{n}$. In the process, we will have taken every $d^{\text {th }}$ number in the period. Thus not only is $\left\{F_{n+d x}, F_{n+d x+j}\right\}$ a Fibonacci subsequence, in a sense it is the same subsequence with a different starting point. We say that it is a "rotation" of the subsequence $\left\{F_{n}, F_{n+j}\right\}$.

In particular, notice that if $\left\{F_{n}, F_{n+j}\right\}$ is a Fibonacci subsequence and $\operatorname{gcd}(j, k(m))=1$, then $\left\{F_{t}, F_{t+j}\right\}$ is a rotation of $\left\{F_{n}, F_{n+j}\right\}$ for any $t$, and the subsequence has $k(m)$ terms.

So how do we find these Fibonacci subsequences? Given only a few successive terms of $\left\{F_{n}, F_{n+j}\right\}$, can we say whether or not it is a Fibonacci subsequence, without having to compute the entire subsequence? As a matter of fact, the main result of this section proves that in many cases we can do just that. Before we present the main result we provide the following two lemmas.

Lemma $4.9\left\{F_{0}, F_{j}\right\}$ is a Fibonacci subsequence if and only if $\left\{F_{n}, F_{n+j}\right\}$ is a Fibonacci subsequence with $F_{n} \equiv 0$.

Proof: The ideas in this proof are similar to those in the proof of theorem 3.25. Let $s$ be the residue of $F_{n+1}(\bmod m)$. The pair $\left(F_{n}, F_{n+1}\right) \equiv$ $s\left(F_{0}, F_{1}\right)(\bmod m)$, hence the sequence $F_{n}, F_{n+1}, F_{n+2}, \ldots(\bmod m)$ is the same as the sequence $s F_{0}, s F_{1}, s F_{2}, \ldots(\bmod m)$. Certainly, if $\left\{F_{0}, F_{j}\right\}$ is a Fibonacci subsequence then $\left\{s F_{0}, s F_{j}\right\}$ is a Fibonacci subsequence, and hence $\left\{F_{n}, F_{n+j}\right\}$ is a Fibonacci subsequence.

In the other direction, we know that $\operatorname{gcd}(s, m)=1$, (this is seen in the remark after identity 3.26 ) therefore there exists a $t$ such that $t\left(F_{n}, F_{n+1}\right) \equiv$ $\left(F_{0}, F_{1}\right)(\bmod m)$, and the result follows as before.

Lemma 4.10 For odd $j, F_{n-j}+F_{n} \equiv F_{n+j}(\bmod m)$ if and only if $\left(L_{j}-1\right) F_{n} \equiv 0(\bmod m)$.
Proof: We make use of identity 2.1, namely $F_{n+j}=L_{j} F_{n}+(-1)^{j+1} F_{n-j}$, in the first line below.

$$
\begin{aligned}
F_{n-j}+F_{n} \equiv F_{n+j} & \Longleftrightarrow F_{n-j}+F_{n} \equiv L_{j} F_{n}+(-1)^{j+1} F_{n-j} \\
& \Longleftrightarrow F_{n} \equiv L_{j} F_{n}(\text { since } j \text { is odd }) \\
& \Longleftrightarrow\left(L_{j}-1\right) F_{n} \equiv 0 \quad(\bmod m) .
\end{aligned}
$$

We are now ready to present the main theorem of this section.

Theorem 4.11 If $F_{j} \equiv F_{2 j}(\bmod m)$, then $\left\{F_{n}, F_{n+j}\right\}$ is a Fibonacci subsequence for all $n$ such that $F_{n} \equiv 0(\bmod m)$.

Proof: We will look at two cases: $j$ is odd and $j$ is even. In each case we will show that $\left\{F_{0}, F_{j}\right\}$ must be a Fibonacci subsequence, then application of lemma 4.9 will imply the conclusion of the theorem.

Case 1: Suppose $j$ is odd.
In lemma 4.10 we can view $\left(L_{j}-1\right) F_{n} \equiv 0(\bmod m)$ as a linear congruence with $F_{n}$ given and $\left(L_{j}-1\right)$ the variable. The solution set of this linear congruence is $\left(L_{j}-1\right) \equiv\left\{0, \frac{m}{d_{n}}, \frac{2 m}{d_{n}}, \frac{3 m}{d_{n}}, \ldots, \frac{\left(d_{n}-1\right) m}{d_{n}}\right\}$ where $d_{n}=\operatorname{gcd}\left(F_{n}, m\right)$. If $\left(L_{j}-1\right)$ is congruent to any of the elements in the set, then the linear congruence will be satisfied. [4, p. 78].

Let $n$ be given. Then

$$
\begin{aligned}
& \left\{\text { odd } j: F_{n-j}+F_{n} \equiv F_{n+j}\right\} \\
= & \left\{\text { odd } j:\left(L_{j}-1\right) \equiv 0, \frac{m}{d_{n}}, \frac{2 m}{d_{n}}, \frac{3 m}{d_{n}}, \ldots, \text { or } \frac{\left(d_{n}-1\right) m}{d_{n}}\right\} .
\end{aligned}
$$

We know that $F_{n} \mid F_{t n}$ so we must have $\operatorname{gcd}\left(F_{n}, m\right) \mid \operatorname{gcd}\left(F_{t n}, m\right)$. Thus, using previous notation, $d_{n} \mid d_{t n}$. It follows that $\left\{0, \frac{m}{d_{n}}, \frac{2 m}{d_{n}}, \ldots, \frac{\left(d_{n}-1\right) m}{d_{n}}\right\} \subseteq\left\{0, \frac{m}{d_{t n}}, \frac{2 m}{d_{t n}}, \ldots, \frac{\left(d_{t n}-1\right) m}{d_{t n}}\right\}$.

Hence, if $j$ is a solution given $n$, then $j$ is a solution given any multiple of $n$. In other words, if $F_{n-j}+F_{n} \equiv F_{n+j}(\bmod m)$ then $F_{t n-j}+F_{t n} \equiv F_{t n+j}(\bmod m)$ for all $t$.

In particular, suppose that $j$ is a solution given $n=j$ (this is exactly what the hypothesis of our theorem supposes). Then $F_{0}+F_{j} \equiv F_{2 j}, F_{j}+F_{2 j} \equiv F_{3 j}$, $F_{2 j}+F_{3 j} \equiv F_{4 j}, \ldots(\bmod m)$. That is, $\left\{F_{0}, F_{j}\right\}$ is a Fibonacci subsequence.

Case 2: Suppose $j$ is even.
First we look at a necessary condition. If we assume that $\left\{F_{0}, F_{j}\right\}$ is, in fact, a Fibonacci subsequence then we must have $F_{j} \equiv F_{0}+F_{-j} \equiv F_{-j}(\bmod m)$. However, we know from identity 1.3 that for even $j, F_{-j}=-F_{j}$, and so we must conclude that $F_{j} \equiv-F_{j}(\bmod m)$. Thus if $m$ is odd we must have $F_{j} \equiv$ $0(\bmod m)$, and if $m$ is even we have either $F_{j} \equiv 0$ or $\frac{m}{2}(\bmod m)$. Hence, the only nontrivial case occurs when $m$ is even and $F_{j} \equiv \frac{m}{2}(\bmod m)$.

Once again, identity 2.1 states that $F_{n+j}=L_{j} F_{n}+(-1)^{j+1} F_{n-j}$. When we let $n=t j-j$ we get $F_{t j}=L_{j} F_{(t-1) j}+(-1)^{j+1} F_{(t-2) j}$. When $t=2$ we get the familiar identity $F_{2 j}=L_{j} F_{j}$, which implies here, $\frac{m}{2} \equiv L_{j}\left(\frac{m}{2}\right)(\bmod m)$. We use this relation to simplify the congruences (taken $\bmod m$ ) below.

$$
\begin{aligned}
F_{3 j} & \equiv L_{j} F_{2 j}-F_{j} \\
& \equiv L_{j}\left(\frac{m}{2}\right)-\left(\frac{m}{2}\right) \equiv 0 \\
F_{4 j} & \equiv L_{j} F_{3 j}-F_{2 j} \\
& \equiv L_{j}(0)-\left(\frac{m}{2}\right) \equiv \frac{m}{2} \\
F_{5 j} & \equiv L_{j} F_{4 j}-F_{3 j} \\
& \equiv L_{j}\left(\frac{m}{2}\right)-(0) \equiv \frac{m}{2}
\end{aligned}
$$

Hence our subsequence $\left\{F_{0}, F_{j}\right\}=0, \frac{m}{2}, \frac{m}{2}, 0, \frac{m}{2}, \frac{m}{2}, \ldots$ will continue on in this manner and $\left\{F_{0}, F_{j}\right\}$ is a Fibonacci subsequence.

Now it is a simple matter to apply lemma 4.9 and see that if $F_{n} \equiv 0(\bmod m)$ then $\left\{F_{n}, F_{n+j}\right\}$ must also be a Fibonacci subsequence.

This result gives us a fairly easy method for finding many of the Fibonacci subsequences of $F(\bmod m)$, if any exist. However, this method may actually give us more than that as the following conjecture asserts.

Conjecture 4.12 If $5 \nmid m$ then every Fibonacci subsequence contains a zero.
If the above conjecture is true, then our method should give us all the Fibonacci subsequences of $F(\bmod m)$ when $5 \nmid m$. It also appears that every time $5 \mid m$ there must be at least one Fibonacci subsequence containing no zeros. This may have something to do with the fact that the period of the Lucas numbers $=k(m)$ when $5 \nmid m$, and $\frac{1}{5} k(m)$ when $5 \mid m$.

We also make the next conjecture, which tests for the existence of a Fibonacci subsequence when we are given four terms in a row and none of them are required to be congruent to zero modulo $m$.

Conjecture 4.13 If $F_{n-j}+F_{n} \equiv F_{n+j}$ and $F_{n}+F_{n+j} \equiv F_{n+2 j}(\bmod m)$ then $\left\{F_{n}, F_{n+j}\right\}$ is a Fibonacci subsequence.

Finding just three consecutive terms of a subsequence which exhibit the Fibonacci recurrence relation is not sufficient to conclude that the subsequence is a Fibonacci subsequence. As a counter example we see that $F_{7}, F_{9}, F_{11}$ are 1,4 , and $5(\bmod 6)$ respectively, but $F_{13} \equiv 5(\bmod 6)$.

One thing that makes this area of research attractive is that these subsequences appear quite frequently. Suppose we don't count rotations as different subsequences, and we don't count trivial subsequences of all zeros or the Fibonacci sequence itself. Then for example we find that $F(\bmod 5)$ contains 8 Fibonacci subsequences, $F(\bmod 6)$ contains 11 Fibonacci subsequences, $F(\bmod 7)$ contains 1 Fibonacci subsequence, and $F(\bmod 10)$ contains 39 Fibonacci subsequences. Table 4.2 lists all the "smallest" pairs $(n, n+j)$ for which $\left\{F_{n}, F_{n+j}\right\}$ is a Fibonacci subsequence modulo 10 . Note that $k(10)=60$ and $\beta(10)=4$.

Finally we mention that not only is the existence of these special subsequences interesting, but how they actually look has its intrigue. We have seen that if a Fibonacci subsequence exits with even spread, then it has the form $\left(\frac{m}{2}\right) \cdot[F(\bmod 2)]$. Every third residue from $F(\bmod 6)$ forms a sequence like $2 \cdot[F(\bmod 3)]$. Every seventh residue from $F(\bmod 91)$ forms a sequence like $F(\bmod 7)$ multiplied through by 13.

|  |  |  |

Table 4.2: Subsequences of $F(\bmod 10)$. The subsequences with asterisks are trivial subsequences, containing only zeros.

Once again, it appears that for every new insight we gain into the Fibonacci sequence, a multitude of new relationships emerge to amaze and intrigue us.
